The great leader of the profession in this country, the elder Dr. Flint, died suddenly of apoplexy in New York city on Saturday, March 13. Dr. Flint was born in Massachusetts October 20, 1812, and had therefore completed his seventy-third year; he had attained a ripe old age, he had lived a life full of honor and usefulness. His ancestors emigrated to this country in 1638, and settled in Concord, Mass. His grandfather, after whom he was named, was a physician, who died at Leicester, Mass., in 1850, having passed the age of ninety years. The dead physician, after pursuing his studies at Amherst and Cambridge for three years, entered the Medical Department of Harvard College, and pursuing a full course, received his degree of M. D. from that institution in 1833. In 1836 he established himself in practice in Buffalo, and in 1844 was appointed to the chair of the Institutes and Practice of Medicine in the Rush Medical College of Chicago; but this position he relinquished at the end of a year. For ten years from 1846, he was the able editor of the *Buffalo Medical Journal*. In 1847, he was one of the founders of the Buffalo Medical College, in which, until 1852, he was Professor of the Principles and Practice of Medicine and of Clinical Medicine. In 1852, he became Professor of the same branch in the University of Louisville, where he remained until 1856, when he returned to the Buffalo College as Professor of Pathology and Clinical Medicine. From 1858 to 1861 he was Prosessor of Clinical Medicine in the Medical School of New Orleans in the winters, having in the meanwhile (in 1859) removed from Buffalo to New York city, where he passed the remainder of his life. In 1861 he was appointed Professor of the Principles and Practice of Medicine and of Clinical Medicine in the Bellevue Hospital Medical College. In 1872 he was elected President of the New York Academy of Medicine. As an author, his contributions are well known to the profession. He has been President of the American Medical Association, and was to have been the President of the International Medical Congress for 1887. He contemplated visiting England this summer to read the address in the section of medicine before the British Medical Association.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to maintain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

FRACTURE OR DISJUNCTION OF UPPER EPIPHYSIS OF HUMERUS; FRACTURE OF THE SHAFT OF THE FEMUR; FRACTURE OF THE FEMUR IN AN INFANT; EXSTROPHY OF THE BLADDER.*

BY H. R. WHARTON, M. D.,

Of Philadelphia,

Surgeon to the Children's Hospital; Instructor in Clinical Surgery in the University of Pennsylvania; Assistant Surgeon to the University Hospital.

The first case I shall bring before you today is this boy, twelve years of age, who is under treatment in the out-patient department of the hospital under the care of Dr. Fox for a rather rare injury of the left humerus, which he received in falling from a wagon a few days ago. Upon removing the dressings and examining the left shoulder, you will notice that it is slightly flattened, that the arm rests against the side of the body, and that there is a slight projection in front of and below the acromion process of the scapula, which moves as I move the shaft of the humerus. I will not subject the patient to the pain necessary to demonstrate to you the existence of fracture, as I am well satisfied as to the nature of the lesion in this case, which is a fracture or disjunction of the upper epiphysis of the humerus. The only other injuries of the humerus with which this condition might be confounded would be a fracture of the upper part of the humerus or a dislocation of the head of the humerus; in the first condition we would have many of the same symptoms present, but would not have the same deformity which we have in this case, namely, a slight projection of the upper end of the shaft of the humerus in front of and below the acromion process of the scapula, the head of the bone taking a position slightly behind and below its normal position with reference to the shaft of the humerus.

From a dislocation of the head of the humerus we make the diagnosis by the exclusion of the symptoms of dislocation, namely, the marked flattening of the shoulder, the prominence of the acromion process, the position of the arm with reference to the body, the immobility and absence of crepitus.

As regards the treatment of this injury, I think that used in cases of fracture of the upper portion of the humerus, known as Ferguson's dressing, is the best, and I will now dress this case before you, so that you can see the method of its application.

I first apply a roller bandage to the arm, starting at the tips of the fingers and carrying it up to the shoulder. I next apply this moulded pasteboard splint, well-padded with cotton, which is moulded to the shoulder and extends down to the lower third of the humerus, and encircles a little more than one-half of the arm. This pasteboard splint is held in position by a roller bandage, which is started at the elbow, is carried up the arm, and is finished by a few spica-of-the-shoulder turns. A small compress is placed over the prominence in front of the shoulder, and held in place by the turns of the bandage last mentioned.

I now apply a folded towel to the axilla

* Delivered at the Children's Hospital.

and side of the chest, and bring the arm to the side of the body and secure it in this position by circular turns of a roller starting at the elbow, carrying it around the body, and ascending to the line of the axilla.

The application of a sling, in which the hand and wrist rest, completes the dressing, and in applying this sling it is well to see that the forearm is not allowed to rest in this, but merely the hand and wrist, so that the weight of the arm between the seat of fracture and point of support of the sling may act as an extending force.

This is a very comfortable and efficient dressing, and is equally serviceable for all fractures high up in the humerus. It should be renewed every other day for a few days in the early stages of the fracture, and afterwards it can be changed at less frequent intervals.

The time required for the treatment of this injury is about four or five weeks, and during the latter part of the treatment passive motion should be practiced at each change of the dressing.

The cure resulting is generally good as regards usefulness of the arm, and although in some cases the resulting deformity is quite marked, I have seldom seen much impairment of the motion of the arm.

FRACTURE OF THE SHAFT OF THE FEMUR.

The next case I bring before you is this little girl seven years of age, who, as the result of a fall, received a fracture of the shaft of the left femur, the seat of fracture being in the middle third.

The important points in the diagnosis of this injury are the loss of function, the shortening, eversion of the foot, and mobility and crepitus at the seat of fracture in the injured limb. The shortening in this form of fracture in children is not so important a diagnostic sign as it is in a similar injury of adults. A fracture of the femur in its upper portion might be confounded with a dislocation of the femur, but in such a case as this, where the seat of fracture is in the middle of the bone, the ordinary symptoms of fracture are so evident that no error could here be made.

I will now measure the injured limb, and upon comparing its measurement with that of its fellow, I find there is less than half an inch shortening; this corresponds with the observation that has been made, that in fractures of the femur in children the shortening is generally very small in amount. This is accounted for in two ways, first that the line of fracture is generally more transverse and the same tendency to over-lapping does not exist as in the more oblique fractures of adults, and second that the muscular action producing shortening is not so powerful in this class of patients.

The dressing which I will apply in this case is the one we generally employ for fracture of the femur in this hospital, and I think you will find it a very satisfactory one. It is applied in the following manner: I first take a broad strip of adhesive plaster, two or two and a half inches in width, and long enough to extend from the outer side of the knee of the injured limb downwards around the sole of the foot, and up the leg to a corresponding point on the inner side. This is held in position by circular straps of adhesive plaster applied around the limb: one just below the knee, one at the middle of the leg, and another just above the malleolli. A small block of thin wood, two inches wide and three inches long, is now applied to the loop of plaster below the foot; this is held in position by a reversed strip of plaster, which serves to hold the block, and as it is carried up just above the malleoli, prevents the adhesive surface of the lateral strips from adhering to these prominences. A perforation is made in this block, into which a cord is fastened, and to which in turn the weight used in making extension is attached, the cord running over a pulley fastened to the lower portion of the bed.

A roller-bandage is next applied, covering in the foot and carried up the leg to the knee, rendering the fixation of the extension apparatus still more secure. We next need some means of furnishing lateral support to the injured limb, and this is furnished by means of these bags filled with bran and by these two wooden splints.

The splints are wrapped in a splint cloth and the long splint is applied to the outer side of the limb, extending from the foot to the axilla; the short one extends from the foot to the perineum; the bran-bags corresponding in length to the splints are now applied between the splints and the limb; these are now held in contact with the limb and body by four or five bands applied around the dressing and firmly tied.

The foot of the bed is next slightly elevated to prevent the patient slipping down, and also to allow the weight of the patient's body to act as a counter-extending force. The dressing is now completed by fastening a weight to the cord attached to the extension apparatus, and in a child of this age, a weight of three or four pounds will be amply sufficient for purposes of extension. This

dressing can be renewed as the parts become disarranged, and is generally kept on for four weeks, when it may be removed and a plaster-of-Paris or pasteboard splint may be applied for a week or two without extension, and at the end of five or six weeks the patient is allowed to get up and walk with the aid of crutches; at the end of eight weeks these may be dispensed with.

We of course expect to get some shortening in all these fractures of the femur, but in children, as I before stated, it is generally very slight, and it has been pointed out by Ollier, of Lyons, that we may even have lengthening of the injured limb, which he explains by the fact that the irritation from the seat of fracture may be transmitted to the lower epiphysis of the bone, increasing the functional activity of the epiphyseal cartilage, and thus causing increased growth of the bone.

Many other methods of dressing may be used; sand-bags may be substituted for the bran-bags and splints, or the plaster-of-Paris dressing, or moulded splints of pasteboard or gutta-percha, or you may use the double inclined plane. By the use of these various means excellent results may be obtained. But I have shown you here the dressing that we use in this hospital in cases of fracture of the femur in children who have passed the period of infancy.

FRACTURE OF THE FEMUR IN AN INFANT.

I am glad in this connection to have the opportunity of showing you this patient, an infant between three and four months of age, who by a fall from its mother's arms sustained a fracture of the right femur, and is also under treatment in the out-patient department of the hospital, under Dr. Fox's care. As the dressings which have been applied are soiled and require renewal, I will now redress the case before you, so that you may see the method we adopt in the treatment of fractures of the femur in infants.

We here employ a pasteboard splint, which is moulded partly around the pelvis and extended down the injured limb to the sole of the foot. This is moistened in hot water and is well padded with cotton, and applied to the limb and pelvis, so that the limb is almost surrounded by this pasteboard gutter, and is held in position by four broad strips of adhesive plaster, encircling the splint and limb, the last one encircling the splint and the pelvis.. While this is being applied, extension is kept up by the hands of an assistant. I now apply a roller bandage, starting it at the foot, carrying it up the limb, and ending it with spica-of-the-groin turns, which include the pelvis; and this completes the dressing.

This dressing need only be changed as it becomes loose or soiled by the evacuations from the bladder or rectum. It is usually kept on for about three weeks, when it is generally found that union is quite firm in the fractured bone and all dressings may be dispensed with.

Here, for obvious reasons, there is not the same danger of consecutive shortening as there would be in an older child or an adult if the dressing were removed and the patient allowed to use the limb too soon. You will notice that we apply no apparatus for making extension in the treatment of these fractures in infants, for the reason that there is very little, if any, tendency to shortening, the muscles having little power to produce this deformity; and also shortening does not result in many cases, from the fact that the fracture is an incomplete one.

Even in complete fractures, as evidenced by the presence of crepitus and preternatural mobility at the seat of fracture, I think the periosteum frequently retains its continuity sufficiently to hold the fragments in good position.

In incomplete fractures, if there is marked deformity, it should be corrected by forcible bending with the hands, and in correcting this, the fracture is frequently converted into a complete one, but this is not a matter of much moment, as a better result is obtained as regards the correction of the deformity if this is accomplished at the primary dressing, and union progresses with equal rapidity.

It is a curious fact how little discomfort these infants appear to suffer from this injury. I have seen several cases in which the injury was undetected at the time of its occurrence, and only attracted the parents' attention as the thigh became swollen from the deposit of callus at the seat of fracture; the accident in these cases took place during delivery, and the patients were not brought to the hospital until ten days or two weeks after that time.

The dressing you have seen applied in this case, which fixes the hip-joint, the knee-joint and the ankle, is a very satisfactory one, as it allows the child to be lifted without disturbing the fragments to take the breast, or when its napkins are changed, which would be impossible were the ordinary dressings which we use in the treatment of this injury in older children applied.

You may, if you prefer, use the plaster-of-

Paris dressing, applied in the same manner, but it becomes so soon soiled by the discharges, that it requires early removal and renewal, both of which are more difficult of accomplishment than in the dressing you have seen applied. The silicate of potassium bandage may also be used in the same manner, but has the same disadvantages as the plaster-of-Paris dressing in its removal and renewal.

We in some cases use a splint moulded from hatter's felt, which acts as well as the pasteboard splint, and is not so liable to absorb or be softened by the discharges.

EXSTROPHY OF THE BLADDER.

I will take this opportunity to call your attention to a congenital deformity which this infant presents, which is known as exstrophy of the bladder, and is supposed to be due to an arrest of development during fœtal life, and consists in the absence of the anterior wall of the bladder, with a corresponding deficiency of the lower part of the abdominal parietes, and often of the pubic symphysis.

In the male, in which this condition occurs with the greatest frequency, the penis is epispadic and poorly developed, and in the female the clitoris is split into two parts, corresponding to the nymphæ, the bladder and urethra opening into or immediately above the vagina.

If you examine this case closely, you will notice this purplish-red mass protruding from the opening in the abdominal walls, which is the posterior wall of the bladder, covered with mucous membrane; the openings of the ureters can be seen at the lower part of this mass, and also the shortened and epispadic penis. You will notice also a hernia on each side, extending into the scrotum. The occurrence of hernia in these cases is quite common.

You see also the excoriated and inflamed condition of the scrotum, perineum, and thighs, from being constantly bathed in the urine, so that upon the whole these patients present a most distressing condition.

Within a few years several operations have been devised and practiced to remedy this unfortunate deformity, and have been employed with a fair amount of success.

One class of operations aim at diverting the course of the urine, and the other class aim by a plastic operation to cover the bladder and put the parts in such a condition that a suitable apparatus may be worn for receiving the urine.

The plastic operation most favorably looked upon for the relief of this deformity is that devised and employed by Mr. Wood, of King's College, London, which consists in taking a somewhat square flap from the umbilical region inverted over the bladder; two flaps are then taken from the groin on each side, twisted and secured over the umbilical flap, and in case of a male subject with epispadia a roof may be made for the urethra at a subsequent operation.

In the case of this child we would not at present recommend any operation, as it is a serious one, and is accompanied by a considerable amount of shock, so that we would rather defer it until the child is a little older.

I am glad to have had the opportunity to show you this case, as it is one of sufficient rarity to make it of interest.

Communications.

THREE CASES OF ACUTE DEMENTIA, WITH RECOVERY: ONE FROM ALCOHOLIC ADDICTION, ONE FROM OPIUM ADDICTION, AND ONE FROM DOUBLE ADDICTION, ALCOHOL AND OPIUM.

BY JOHN S. MARSHALL, M. D.,

Supt. Sanitarium and Water-Cure, Green Spring, Ohio.

During ten years' experience in the treatment of alcohol and opium habitues, there have come under the writer's observation three cases whose history and recovery are quite out of the ordinary line, and therefore may prove interesting to your readers. Mr. A., æt. 25, Pa., single, law student, was admitted in April, 1883, with the following family history: The father was a moderate drinker, and died at the age of 55 from apoplexy. The patient has three brothers, one of whom is strictly temperate, one is a moderate drinker, and the third is a confirmed inebriate. One maternal uncle died from the effect of drink, another is an inmate of an insane asylum as the result of drink. At the time of admission, and for six years immediately preceding, the excessive use of stimulants had been almost constant. Upon first examination there was present a condition bordering on delirium, with insomnia, an irritable pulse, white-furred tongue, tremor of hands, and constipation. Stimulants were continued for five days in gradually diminished quantity. In addition, tonics, hot-baths, and other sedatives were given. At the end of the third day there developed delusions complicated

with hallucinations of sight, hearing, and feeling. During the first week he became very restless, with the constant delusion that he was aboard a train and had lost his ticket, and that the conductor was about to put him off in his night apparel. The remedy which most effectually relieved this restlessness and insomnia was the very hot tub-bath, temperature 110° to 115° F., alternating with the electro-thermal bath. As time passed, his mental faculties failed, resulting in an acute dementia, with less pronounced delusions and hallucinations. For seven weeks from this time he failed to recognize the doctor, attendant, or his friends. His excretions passed uncontrolled by will. He was unable to feed himself, and in general refused food, except a limited quantity of liquids given with a spoon. Any attempt to converse with him elicited incoherent answers, showing an almost entire suspension of ideation. Accompanying this mental condition there existed an incoherency of muscular action. Not unfrequently he would wrap his bedding about him and wander around the room for hours, feeling carefully of every article of furniture, without the least idea of its use or value. At the end of seven weeks the first evidence of improvement was noticed. The facial expression was changed from a non-expressive and demented appearance to that of a calm and thoughtful one; answers to questions were generally rational, but in monosyllables, with a decided tendency to melancholia. Improvement continued during the following four weeks, and twelve weeks from date of admission his recovery was complete. The later treatment consisted of a good nourishing diet, supplemented with tonics, baths, and massage.

Mr. B., æt. 30, Ohio, married, physician, admitted to Sanitarium in June, 1884. The family history, so far as could be learned, had no special bearing upon the case. He was a quiet and industrious young man, with no tendency to excesses of any kind. He practiced his profession for six years immediately following graduation, when poor health led him to seek another climate. His choice was the high and dry lands of Colorado. Soon after reaching his destination, he suffered from dysentery, for which he used morphia. Upon the eve of recovery from dysentery, he had an attack of inflammatory rheumatism running four weeks, for which morphia, hypodermically, was administered. In due time he recovered from the rheumatism, but with recovery failed to discontinue the use of morphia, which had now become a fixed habit. The use of the drug gradually grew upon him, until at the end of two years he came to us for relief, with a history of having taken from twenty to thirty grains daily for six months just previous. A few days prior to his admission, the friends noticed a slight change in his mental condition. In an attempt to say something, he would utter three or four words and stop, and make a second attempt, usually with better success. Accompanying the mental failure there appeared a muscular incoördination, involving, particularly, the extremities. His gait was very similar to that of a drunken man. In an effort to take a cup from the table he would reach for it and miss it. This was his condition when first seen by the writer. As the mental aberration grew worse, the appetite for morphia grew less, until, at the end of two weeks from the beginning of the mental derangement, the system failed to respond to the stimulus of the drug, and consequently the craving for it ceased. The result was a gradual development into acute dementia, with almost complete muscular and mental incoördination.

This case differed from the preceding one in that there were no clearly-marked delusions or hallucinations. During the entire attack he remained entirely passive, offering no resistance to anything that was done for him. The calls of nature were responded to only by the stimulus of going to stool, as were those of eating by the assistance of the attendant in feeding him. By persistence in a liberal diet, the use of tonics, stimulating baths (water and electro-thermal), and massage, continuously for four weeks, the light of a new mental world began to dawn upon him; and so rapid was his recovery that at the end of ten weeks from date of admission, he was discharged, and at the present time is well and doing a fair practice.

Mrs. C., æt. 33, Iowa, married, housewife, mother of three children, the youngest three years of age. Her second confinement was a tedious one, resulting in poor health for many months immediately following. In the course of treatment, the physician prescribed a glass of ale three times daily. The direction was followed for months purely as a medicine. In due time she recovered her health, but with the recovery failed to omit the ale, and at the end of a year from date of confinement, the habit had become fixed with her. She grew rapidly in flesh from 135 to 195 pounds. Her third and last confinement was an easy one, but seemingly from the beginning of the last gestation,

four years ago, there was a noticeable change in her mental condition. She became so irritable at times that she would throw her children about, regardless of their feelings. During one of these fits of temper, as her husband called them, he shut her in a room to prevent possible injury to the children. The experiment resulted in her breaking everything in the room, even the door of exit. These apparently concealed epileptoid furors increased both in frequency and severity, until during the last two years there was a regular series of such scenes as the one just related. While her husband is a gentleman of culture and refinement, and withal most circumspect in his conduct, yet if she were overcome by one of these furors at a public entertainment, she would stop short in the midst of a dance, perhaps, and compel the husband unceremoniously to go home, and the remainder of the night would be devoted to an almost continuous stream of abuse against him for undue familiarity with other ladies. She even compelled a younger sister who was living with her to leave, because of jealousy. During 1884 she suffered greatly from temporal neuralgia, coming on in the after part of the day, and becoming most severe about bed-hour. It was her habit at that time to take a bottle of ale during the day, and from one to three between tea and bed-hour. The headaches reached such a degree of severity that she felt compelled to resort to something which would both relieve pain and produce sleep. Early in 1884, and for some time before her husband had any knowledge of the fact, she was taking Brown-Sequard's anti-neuralgic pills. At first it was her custom to take from one to three of these pills during the night, but as their effect grew less she gradually increased the number, and later admitted having taken seven in a single night. When she was unable to procure the pills, her husband was persistently importuned to get something for her relief, until, to preserve peace, he would apply to a physician, who usually gave a preparation containing some form of opium. Thus she continued the double addiction for a year prior to admission to the Sanitarium in January, 1885. She came voluntarily and alone, and expressed herself as willing and anxious to get rid of a most unfortunate habit. When at her best mentally, she expressed herself freely concerning her husband, and admitted him to be a most excellent man and at the same time much abused by her jealous epithets. Upon admission, the ale was discontinued, and instead, stimulating doses of the fluid extract of coca with quinine and nux vomica. At the end of a week the coca was omitted and the tonic continued. As was to be anticipated, she complained almost continually of headache, for which I gave an anodyne, consisting of cannabis indica, conium, sodium bromide, and chloral hydrate, and found she took readily to anything of this nature, which would relieve pain or in the main supplant the effect of morphia. At the end of four weeks all stimulants and sedative medicines were discontinued, and we were left to rely wholly upon the sedative influence of the various baths and massage. The furors came and went with unabated energy. The doctor, the matron, the attendant, and all who had to do with her, shared the fate of the husband. It was with the greatest difficulty the writer could convince the attendants that these freaks resulted from a disordered brain, and not wholly from an ill temper. They were of one accord in their desire to be relieved from attending to her wants, which were almost without number, and the most unreasonable. Two weeks after all stimulants had been withdrawn, one of her furors culminated in a collapse of the mental faculties, accompanied by delusions and hallucinations. Most prominent among the latter was the one that electricity was continually being carried into the room over the wire of the electric call-bell, and unless a method of escape were offered it, she would soon succumb to its influence. Possessed with this hallucination, she would raise the window full, with the thermometer 15° below zero, and stand by the hour with the body exposed, if allowed. When the window was securely closed, she would kick the glass out. Another dominant hallucination was that a number of children, among them hers, were locked in the basement, and their cries annoyed her night and day. Owing to these hallucinations, and for two weeks from date of their development, she was very demonstrative, and required vigilant care to prevent accident to herself and the destruction of furniture. Food and medicine were refused a greater portion of this time. Immediately following this period of excitement, she gradually settled into dementia, remained in bed, except as she was assisted about by the attendant, and ate only as she was fed. She remained substantially in this condition for three months. Her husband came and remained four weeks, during which time she failed to recognize him. When he left, discouraged as he was, I gave him a favorable prognosis, and for further encouragement related

the history and result of the preceding two cases. At the beginning of the fourth month a favorable mental change was perceptible. One noticeable and interesting feature in her improvement was that as she began to emerge from the dementia, her first rational ideas reverted to the persons and transactions which last concerned her just preceding the mental collapse. The mental impressions last made were the first to be revived. After three months of almost complete inertia of the brain, those thoughts which occupied the mind when ideation was first suspended, were reproduced to her as vividly as though but twenty-four hours had intervened. As time passed, older brain impressions were revived in almost the exact reverse order of registration, until at the end of two weeks from the beginning of her improvement she, for the first time, inquired for the husband and children whom she had not seen for about six months, and consequently impressions registered six months previous to the collapse were two weeks in being revived after improvement began. She continued to grow mentally strong without hindrance, and when she learned of her husband's intended visit the middle of June, she anticipated it with pleasure. She left us the first of July, feeling that she had been amply repaid for the sacrifice made in ridding herself of the double narcotic addiction.

From a history of the three cases just related, the following observations may be noted. In young persons with a comparatively good constitution, in which the habit has been formed within a recent period of a few years, and acute dementia accompanies or supervenes on withdrawal of the stimulant, the prognosis is favorable. In persons of middle life, or older, with a habit of many years' duration, accompanied by dementia, and in whom the brain ceases to respond to stimulants, the prognosis is unfavorable. In confirmation of the latter statement, the writer has at present an opium habitué who was admitted in July, 1884, æt. 41, druggist, the habit dating back ten years. There had been no inclination to take the drug for six weeks just preceding his admission. For years before, it was his custom to take from one-half to one pint of laudanum daily. He was admitted in a state of dementia which lasted nine months, and from which he has partially recovered, but still has both delusions and hallucinations. The prognosis in this case must necessarily be guarded, as the indications already point to existing organic cerebral changes.

Another illustration may be found in the case of a woman admitted in March, 1885, æt. 55, with a history of having taken from five to ten grains of morphia for fifteen to eighteen years. When admitted her condition was a most lamentable one. She was completely demented, and unable to recognize her daughters. She required as much attention as an infant, and six months later, without any indications of improvement, death came to her relief.

Another observation may be noted: where stimulants and anodynes are indicated and prescribed, the general tendency in the profession is to ignore or overlook the danger to be apprehended. In nine cases out of ten the foundation for the opium habit is laid by the physician's prescription. This prescription, the contents of which is often unknown to the patient, is filled and refilled, until the habit is insidiously fixed and controls the patient. The writer is more impressed year by year with the apparent carelessness of physicians in giving dangerous prescriptions to their patients. If every practitioner will exercise the utmost caution in the use of these drugs, and will observe carefully the effect and also the tendency of his patient, and omit their use at the earliest possible moment, we shall have a smaller number of habitués.

In conclusion, I desire to emphasize the very satisfactory results obtained by the liberal use of baths and massage, as an element in the treatment of both alcoholic and opium cases.

SEVEN CASES OF DIGITAL EXPLORATION OF THE BLADDER IN THE MALE,*

BY WILLIAM T. BELFIELD, M. D.,

Of Chicago.

Case 1. A patient 58 years old, who had been treated for several years, by various physicians, for cystitis and prostatic enlargement; complete retention had occurred several times. A diagnosis of villous tumor of the prostate was made, the nature of the growth being predicated upon the semi-gelatinous state which the urine presented after standing for a few minutes—an almost pathognomonic symptom when present. Exploration revealed a small villous growth just to the left of the urethral orifice in the bladder; and imbedded in its meshes were found two stones, as large as a pea and a bean respectively, whose existence had not been suspected. Patient made a rapid recovery, and

*Read before the Chicago Medical Society. (Abstract)

was entirely free from his old complaint three months afterwards.

Case 2. A boy 17 years old had for two years suffered from frequent and painful urination, during which time considerable pus was constantly present in the urine. A probable diagnosis of tuberculosis of the urinary tract was made, and was confirmed some time afterward by the discovery of the characteristic bacilli in the urinary pus. At the urgent request of the parent the bladder was explored, with negative result. Some months afterwards nodular enlargement of the prostate and epididymis were developed. Patient's symptoms unimproved by the operation.

Case 3. A man 63 years old, in the last stages of chronic cystitis, was admitted to the county hospital. Had been treated for enlarged prostate. No enlargement of this gland could be recognized, but there was found, upon rectal examination, a collection of calculi occupying the exact site of the left seminal vesicle. Upon exploration of the bladder it was found that these calculi were contained not in the vesicle, but in a diverticulum of the bladder, where they were completely encysted and covered with mucous membrane. This covering was torn and seventeen stones were removed. The patient's condition was much improved for two weeks after the operation, but at the end of six weeks he died.

Case 4. A man 38 years old, suffering from all the symptoms of an extremely tight stricture of the deep urethra. No stricture could be found. Upon exploration of the bladder there was discovered a pedicled cyst attached to the upper orifice of the urethral opening, and completely occluding the urethra like a valve; the tumor appeared to be as large as a small walnut. During an attempt at removal with forceps the cyst collapsed, about half an ounce of clear fluid escaping. The patient recovered rapidly, and has since remained quite free from urinary irregularities. This appears to be the first recorded instance of simple cyst in the male bladder.

Case 5. A patient 38 years old, admitted to hospital in a typhoid condition, suffering from cysto-pyelitis, for which no cause was discovered. Exploration of the bladder showed nothing abnormal. The cystitis and pyelitis subsided completely. When patient was able to leave the hospital, it was discovered that he was suffering from an incipient myelitis.

Case 6. A man 31 years old, admitted to hospital with violent and fetid cystitis. It was found impossible to pass any instrument over a prostatic obstruction into the bladder; from the rectum the prostate was found irregularly enlarged. Upon exploration of the bladder, a malignant tumor, involving the prostate and a large part of the bladder wall was discovered. Complete anuria ensued, and death from uræmia on the fourth day. At the autopsy, hydronephrosis of the left kidney, caused by a pipe-stem calculus of the ureter, was discovered.

Case 7. A man 59 years old was admitted to the hospital for a chronic cystitis of fifteen years' standing, caused by prostatic enlargement. Perineal incision was made for temporary relief. Three weeks later a portion of the obstructing prostate was removed through the perineal wound by the galvanocautery. Complete recovery; the patient, who had for two years been practically unable to urinate except through a catheter, now passed water freely without assistance: the cystitis subsided. Nine months afterwards, acute uræmia and death. At the autopsy, small cirrhotic kidneys were found. This is believed to be the first case recorded in which a considerable portion of the hypertrophied prostate has been deliberately and intentionally removed.

On concluding his paper, Dr. Belfield spoke of a case which came into the hospital in a state of extreme exhaustion, evidencing violent cystitis. Urine containing pus was passed every fifteen minutes, with extreme pain. It was impossible to get an instrument into the bladder more than half an an inch. The man was half unconscious, and could give no history, but by rectal examination it was discovered that the prostate was very much enlarged in the left lobe, the right lobe appearing normal in consistency and size. The doctor thought this almost a proof that in a man of this age, 31, the seeds of tuberculous disease were present. The bladder was opened, and the finger inserted in the usual way, discovering a malignant growth covering an inch and a half of the left wall of the bladder. After the operation the patient passed half an ounce of urine, but died in three days from uræmia. The bladder and kidneys were secured and found to be the seat of extensive hyperinosis, caused by a calculus. Another case was that of an emaciated French Canadian, who had had trouble for eighteen years, and had depended entirely for urination upon the catheter for two years. The usual perineal incision was made, and a portion of the prostate removed. The operation was successful, and the man was able to do without the catheter, although Dr. Belfield advised its

use once a day. In June he had a slight attack of cystitis, due to the fact that he had persisted in ignoring the advice in regard to the use of the catheter. About the 10th of September he was taken with uræmic convulsions, and died on the 18th. The last few days the urine became cloudy again. The bladder and kidneys were secured, and a channel found in the prostate large enough to admit the forefinger. Dr. Belfield thought it would have been better to have cut down from above in the hope of relieving the prostatic tumor.

Hospital Reports.

PENNSYLVANIA HOSPITAL.

Service of Dr. Morris Longstreth.

Specimens of Tuberculosis.

I want to show you first to-day some very interesting specimens from a case of tuberculosis, interesting because of the doubt that attended the case from a diagnostic point of view. You will some time or other, no doubt, encounter such a case as this, and you will find yourself surrounded by all manner of doubt in coming to a conclusion as to the nature of the disease that is troubling your patient. The patient, who died but a day or two ago, had been in the hospital since the 24th of last November, and from her history we learned that she had been taken sick three weeks before that date. We were unable to communicate with her for a very unusual cause; we have frequently in the hospital Italians, whom other Italians cannot comprehend because they use some peculiar dialect, but in this case the difficulty of communication arose from the fact that the woman could only speak Irish, and it was only for a few days that we happened to have a person in the hospital who was able to converse in this nearly extinct language. During this brief time, we found out that while hard at work, having been well before (though you must learn that this is a very relative expression, some persons considering themselves well when they are not confined to bed), she caught cold at a menstrual period, in consequence of which she was compelled to abandon work. Her principal complaint was severe pain in the abdomen, and when she came into the hospital there was very great abdominal effusion, in consequence of which the diaphragm was pushed up and there was great shortness of breath. The pain was mostly in the region of the liver, and at that time there was considerable jaundice. It looked very much like a case of peritonitis and perihepatitis, which, by causing pressure on the bile ducts, gave rise to the jaundice. The condition of the effusion varied very much, being sometimes greater and at others lesser. At one time there was a pleural effusion, not merely a dropsy but also a true inflammation, for we could hear friction sounds at the base of the chest on both sides. There was steadily progressing emaciation, without the occurrence of any other special features save the general symptoms that I have indicated. Dr. Da Costa, under whom the patient was for a time, concluded that there must be tubercular disease, but the question was as to where the disease was located and what was its origin. The post-mortem helps us somewhat in arriving at a conclusion. We should say that as a result of the cold the woman had peritonitis, the occurrence of which was favored by the fact that the cold was contracted during the menstrual period, when, of course, all the abdominal viscera are engorged with blood. Now, we must recognize the fact that before tubercle can be deposited in any part there must be a suitable soil generated therein, at least before the tubercle will thrive and multiply. Cheesy degeneration or chronic inflammation will so change a part as to make it congenial soil for tubercle, and these changes may, of course, occur indifferently on either serous or mucous membranes. This supplies the necessary basis for the miliary deposits; some breaking down of the products of inflammation, which condition must necessarily pre-exist. This fact was never doubted until Koch came forth with his doctrine of the etiological significance of the bacillus; but in spite of these recent alleged discoveries, the anatomical fact still remains that we must have this condition to favor the deposit of tubercle. In this case we must look to the peritoneal cavity as the seat of the inflammation that has caused these necessary changes. The greatest amount of tubercular deposit is to be noted in the upper part of the abdomen, which is what we would have a right to expect, for it is in the upper part that we have the most clogging, the most interference with the circulation, the lower part being especially occupied with the serum. The principal adhesions are found about the liver, duodenum, and stomach, and it was in this region that the woman suffered the most pain and that there seemed to be the greatest interference with the proper performance of function, and this very fact served to mislead us in reference to the nature of the

case. See this tubercular deposit over the peritoneum. In some cases the tubercles will run together. There is one symptom of abdominal tuberculosis that is nearly always present; I refer to diarrhœa, which is caused by tubercular ulceration of the intestine. This symptom was wanting here, for, as I have said, nearly all the symptoms that we had were progressive emaciation, pain, and at one time jaundice. We now know why there was no diarrhœa during life, because we find that there is no ulceration of the intestine. Here you see these black spots in the rectum, which indicate that ulceration would have soon occurred, but it had not yet taken place. When we look at the spleen, we find that it is the seat of chronic inflammation, there is not very much tubercular deposit, but the capsule is greatly thickened. The spleen is such a fixed organ, it is so little movable, that when inflammation occurs in its vicinity it is very apt to be bound down by the organization of the inflammatory deposits. Even when, by the naked eye, you cannot see tubercle, you can feel it; when you pass your hand over the surface of an organ, they feel like grains of sand. During life the stomach was irritable and refused food, but the act of swallowing was not accompanied by any pain. We do not find any marked changes in the stomach; the coats are somewhat thickened, the surface congested, but there is no ulceration, no black spots. Let us now turn to the liver. The pressure caused by the effusion has forced the liver up and compressed it, so you see what a peculiar shape it has assumed. On the under surface, about the site of the gall-bladder, there is a mass of inflammatory matter and a deposit of tubercle, and this fact explains to us the occasional occurrence of jaundice, for we can understand how the pressure thus exerted would sometimes interfere with the outflow of bile, which would be then retained, re-absorbed, and jaundice would result. In some cases of chronic peritonitis, there is an enlargement of the lymphatic glands, and if this should occur in those that are located along the course of the duct, even though there may be no adhesions, we can understand how and why jaundice will sometimes occur even in simple chronic peritonitis. We can press the bile out here, because the releasement that is allowed by the removal of the organ enables us to do so, because in this case there has been no actual diminution in the calibre of the duct, but the obstruction has been caused entirely by pressure from without. The liver is very fatty; you can see when I make a section how the oil globules show on the blade of my knife. During life there were no symptoms referable to the kidneys, and as we therefore supposed, we do not find anything wrong with them. The capsule is somewhat thickened, but this is purely an external affair, due solely to the peritonitis; the capsule is not at all adherent, and you see I can readily detach this extra inflammatory layer. When we come to the lungs, we find, as we had supposed, that there has been a pleurisy, and I can pick up a layer of the pleural surface that has become very much thickened. There are a few tubercles in the lungs, but the principal condition that we note is that of pressure. Here is a fresh tubercle; you see the white spot in the centre, with a little circle of redness surrounding it; there is an interference with the circulation and a consequent congestion, almost like an abscess. When still fresher, we see only a red spot, the white spot being discoverable only by the microscope. This case teaches us a very important lesson in reference to diagnosis, as to cause in cases of chronic peritonitis.

Chronic Meningitis.

This case I bring before you to call your attention to the results of treatment. The patient is a married woman, aged twenty-four. Since she has been in the hospital she has been suffering from chronic meningitis, and at one time her case seemed perfectly hopeless, most likely from the point of view of saving life, and almost surely from the view of a restoration to mental soundness and usefulness, even though life might be saved. About the only mental effect of her illness that now remains is that she persistently denies that she is married. Ten years ago she had some kind of a continued fever, coming on after a prolonged exposure to the sun, but we are not able to say whether the fever was the result of this exposure, or even a coincidence. At all events, she surely suffered either from cerebro-spinal meningitis, or from the effects of sun on the brain, either of which suppositions is admissible. When the nervous centres were once so profoundly affected they would be very liable to future derangement when there was a cause. The present attack was ushered in by the ordinary prodromes; there was fever for a week, or may be two weeks, before the attack. The disease commenced last October, when there was, as I have said, continued fever, and diarrhœa, that closely resembled the prodromes of typhoid fever. The temperature record shows us that the fever was about at an end when she came into the hospital, and

it was dropping down just as we see it in typhoid. Hence, we were excusable in supposing that we had to do with a case of typhoid fever. The temperature remained about normal until November 10 (she came in on October 23), when the head symptoms commenced. On that date there was a rise in temperature, and she became delirious. We at first thought that she was experiencing a relapse of the typhoid fever, but the principal phenomena, the head symptoms and the course of the temperature, did not bear out this idea. The fever was very irregular, and she was at all times delirious, sometimes violent. There was great tenderness about the neck; in fine, there were all the evidences of an active meningitis. She was placed on a water bed, for bed-sores were developing. As soon as we recognized the meningitis she was placed upon the use of iodide of potassium, which was continued; but about the middle of January the case seemed absolutely hopeless. We could not communicate with her, and we felt that we could do nothing more. She lay in bed as stiff as a log, with bed-sores all over her, wherever there was pressure; and indeed I cannot too strongly picture her desperate condition. At this time the iodide was stopped, because it seemed to derange the stomach, and because we regarded the case as hopeless. But shortly thereafter an improvement was noted, and as fresh hope was inspired we commenced to give her Fowler's solution, and while the greatest improvement was noted during its use, yet I think the prolonged use of the iodide did the most good. Have you ever seen a brain covered with thick lymph, the nerves covered, almost strangulated, as they emerged?—if so, you can readily understand this woman's condition; the ventricles were also probably full of liquid, so that there was also pressure from within as well as from without; the brain was in a vise, as it were; she was literally without a mind, she was leading a vegetative existence. After the active inflammation has exhausted itself, then, of course, there is a great deal of lymph, which, in organizing, tends to contract. To get rid of this effused lymph there is nothing better than iodide of potassium. The first evidence of improvement, after the woman had been in this vegetative state for a long time, was a desire to read; following this came an ability to walk. As you see, she does not walk very well now, but this I attribute to the fact that she has on a pair of ill-fitting, much-worn slippers. I want to caution you about this point. I once had a case where I had nearly diagnosed a grave nervous disease from the patient's locomotion, when, upon further examination, I found that she had on a pair of shoes where one heel was good and one was much worn, which accounted for the peculiarity in the walking. All her functions are now doing well. There is one other instructive point to which I forgot to call your attention. In the earliest days of the disease, when she first came in, she complained of her mouth; I looked at her tongue and lips (the neck was too stiff for me to examine the throat), and I found a violent stomatitis, which was caused by the presence of false teeth, which, owing to the sickness, had not been cleaned. This is a point that you should always remember; when administering ether, always remove any false teeth, lest they may be swallowed or fall into the windpipe; when one is taken sick among strangers, the last thing they would think of would be the presence of false teeth. It may be that there is not a full set of false teeth, but only one or two, and you cannot imagine how much trouble they may cause.

The Finger-nails in Disease.

Here is another patient with whom we have not been able to communicate. I bring her before you, not because I know very much about the case, but because I want to call your attention to the fact to which I have referred in previous lectures, that there is considerable significance to be attached to the conditions of the nails in disease. She is a Russian girl, about fifteen years of age, who was brought into the hospital yesterday. She had been working very hard, lifting heavy weights, and about four weeks ago she commenced to suffer very much from headache; she became pallid, and was troubled with shortness of breath. I do not know whether she had any fever at that time, but in her finger-nails I read the record that she has been in poor health for some time. She is pale and anæmic, and has a whitish tongue. Such conditions are very common, and when you are in doubt about whether a patient has been really ill for some time or not, always look at the nails. They will tell the history. Suppose, for instance, the patient is a man whose work compels him to have his hands in something that will stain the nails; if he tells you that he has been unable to work for six weeks, you will know he is not telling the truth if you find the nails completely stained down to the matrix; if his hands have been away from work, that part of the nail that has grown since his absence from work will be clean. I once had a sailor

who desired to pretend that he was sick until after his ship left port, that he might escape the voyage; he claimed that he had been unable to work for some time, but his pretense was discovered by the fact that his nails were stained all the way down from the handling of tarry ropes. In this girl's nails about the base there is a space, a depression; and when I speak of a depression I do not refer to the usual white place always noted about the base of the nail, but a true depression. I see it less plainly on the thumb-nail, because this nail grows more slowly than the nails of the fingers. These depressions evidence an interference with the nutrition of the nails, which is a part of the general interference with nutrition, dependent upon the lowered vitality of the patient. Simply seeing these depressions on one hand, however, does not tell the whole story, for they might be due to the fact that the bones of one arm had been broken; but when we have them on both hands, and on the feet as well, we know that there has been some general disturbance. If one finger only is involved in the trouble, then we will have the depression confined to that one nail. The markings are not distinct enough here to warrant me in supposing that the girl has had a continued fever, so that I am inclined to think that she has been overworked and that her nutrition has suffered in consequence.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

Service of D. Hayes Agnew, M. D.

Green-Stick Fracture.

This little child fell off a chair and we have a very fair example of a green-stick fracture, which you understand to be a condition of affairs where only one-half of the fibres of the bone are broken, the others being bent, so that the limb (in this case it is the arm), while bent, is yet fixed in that position, and there is not the mobility of a true fracture. Now I grasp the arm with both hands, and placing my thumbs against the deformity, endeavor to forcibly straighten it. Now I hear the fibres yielding as the bone becomes straight. I will place two little splints on the arm, and we are done.

Here is another case very similar to the last, the accident having occurred four weeks ago. Having been so long out of position, I may not be able to accomplish straightening as readily in this case as I did in the last; but if I cannot I will apply two splints and applying them tighter and tighter, gradually day by day, ultimately we will secure reduction. Such is not necessary here, for you see I have secured reduction the same as I did in the first case, and the dressing will be the same.

Wen.

Here is a little tumor in the cheek; it is cystic, and I will tell you that such swellings are very common on the face. Owing to the adherence of some foreign matter or of an inflammation, the orifice of a sebaceous gland becomes occluded; as a consequence the secretion of the gland becomes imprisoned, it accumulates, distends the follicle, and thus we have the tumor formed. If it is allowed to remain, sometimes an inflammation will develop which will glue the sac to the skin, then the skin will inflame and an abscess will result. We may empty these sacs, but they will fill again; and the trouble will never be thoroughly removed until we perform a radical operation, which consists in the removal of the sac; we must remove the cyst. I apply ice to the tumor to benumb the sensibility. If it happens that during the operation you should empty the cyst so that it becomes collapsed, then it will be necessary for you to distend it with lint in order that you may dissect the sac away. While all operations about the face usually heal nicely, yet it is better that you should provide drainage; for you know that erysipelas of a dangerous character, that may extend to the brain, is not uncommon after traumatisms about the face. To secure this drainage we can use a few threads of catgut, which I think is better than a tube.

Carcinoma of the Breast.

To-day I propose to operate upon this case of carcinoma of the mammary gland. You will remember that I showed you the patient a week ago, when she first came into the hospital, but she was then so much run down that I concluded that it would be better to wait until I had given her some preparatory treatment in the way of building up, before I attempted to operate. The history of the case is that the disease commenced about a year ago; for a while it was stationary, but lately it has grown very rapidly, and the woman complains of the characteristic shooting, radiating pain, so commonly seen in cancer. There is no involvement of the axillary glands that can be detected by pressure, though of course we cannot always so tell whether they are involved or not. I would lay down the rule that when, as you proceed in the operation, you find that the axillary glands are involved, you should re-

move them all; not merely those that are obviously affected, but *all*—because, though some of them may not be affected to the eye, yet the germs of disease may lurk therein, and they may serve as a nidus for the further spread of the disease. There is no disease that is more irregular in its course than is carcinoma; no two cases are alike, and you must be prepared for this diversity, else you will be deceived in your diagnosis. Some cases are very slow and tardy in their growth, while others grow very rapidly. In some cases there is atrophy, in some hypertrophy of the mammary structure. In chronic cases, that are not progressing, my advice would be to let the knife alone, not to touch the case. I would say that the rule is that an operation never prolongs life; it is justifiable because it relieves the mental worriment that the disease occasions, but it will not prolong life. Women quacks and certain cancer doctors will recommend the removal of the cancer by caustic, but such a procedure will cause very great pain, and will leave a very large ulcerating surface. I would say, as a general rule, that the comfort of life is increased by the operation. When I am asked whether the disease is likely to recur after operation, I always answer that it is sure to develop again somewhere. I have had one case where a period of fifteen months, another where ten months, and a third where one year had elapsed since the operation; but in these cases no careful microscopical examination had been made, hence I am in doubt about the correctness of the diagnosis; for I would enunciate the rule that in those cases, of which we occasionally hear, where eight or ten years have elapsed since the operation, without a recurrence, there has been a mistake in diagnosis. But this makes no difference really, for there are many cases of non-malignant growths where removal will be properly called for. Look at the surface of this breast; see, it is smooth, there are no nodules, it might be mistaken for a sarcoma; but we have one very distinctive and characteristic feature in the adherence of the skin, which is rare in sarcoma and very common in carcinoma, even from the very early history of the case. In such cases the skin is implicated, and it must therefore be sacrificed. We will often see little papillæ over it, which mark the site of the follicles.

—A Berlin woman lately attempted to kill herself by drinking five ounces of kerosene. She became unconscious, but was fully restored to health in three or four days.

Medical Societies.

PHILADELPHIA CLINICAL SOCIETY.

Stated meeting, January 22, 1886. The President, Dr. E. E. Montgomery, in the chair.

The following officers were elected for the ensuing year:

President.—Dr. John B. Roberts.

First Vice-President.—Dr. Clara Marshall.

Second Vice-President.—Dr. Daniel Longaker.

Treasurer.—Dr. L. Brewer Hall.

Recording Secretary.—Dr. I. G. Heilman.

Corresponding Secretary.—Dr. Rebecca S. Hunt.

Reporting Secretary.—Dr. Mary Willits.

Councillors.—Drs. Henry Beates, Troth, Henry Hartshorne, Hanna T. Croasdale, Susan P. Stackhouse.

Occlusion of Steno's Duct.

Dr. John B. Roberts mentioned a case in which there was a transudation of fluid on the cheek, in the region of the parotid gland, during mastication. On examination of the buccal opening of Steno's duct a muco-purulent fluid was pressed out. A probe was introduced into the duct for an inch or more, and the canal stretched. On the return of the patient, a day later, he reported that the transudation was less than it had been. The duct was again dilated with the probe. No calculus was found either time the probe was used. The patient had suffered from an abscess in this region three or four years ago, but the cicatrix did not seem to be located over the line of Steno's duct. On the introduction of the probe into the duct an inch or more, the end could be distinctly felt through the skin of the cheek, but it may not have been abnormally perceptible.

Dr. Roberts said that he did not understand the pathology of the case, but believed the fluid to be saliva. He had intended to collect some for chemical testing on blotting paper, but the patient returned to the country. Perhaps the occlusion of Steno's duct was due to inflammatory changes—a catarrh, in fact—and the occlusion dammed up the saliva, which in some may, by effect of pressure, found its way into the sudoriferous and sebaceous glands or ducts, and thus reached the surface.

Dr. Henry Hartshorne said that he had seen such a case while he was a student of medicine. The exudation was in the region of Steno's duct, and there was moisture

enough to necessitate its removal by the handkerchief. He could not remember whether it occurred only *during* mastication or not.

Dr. Clara Marshall said that in reading the article on belladonna in Ringer's *Hand-Book of Therapeutics*, she noticed the following statement:

"In the curious case of a middle-aged man who suffered from excessive sweating of both cheeks while eating, the sweating ceasing immediately after the meal, ten drops of tincture of belladonna thrice daily checked the sweating completely."

It is barely possible that in *this* case the secretion was a transudation of saliva.

Mary Willits, M. D.,
Reporting Secretary.
1527 *Green street.*

NEW YORK ACADEMY OF MEDICINE.

Regular meeting, February 4, 1886. A. Jacobi, M. D., President, in the chair.

The Intra-Cerebral Tracts: Their Physiology, and its Bearing upon the Diagnosis of Lesions of the Centrum Semi-Ovale.

Dr. M. Allen Starr read a paper with this title, which was followed by one on

Permanent Drainage in Ascites.

By Dr. Aug. G. Caillé, who preceded his general remarks by the histories of two cases of cirrhosis of the liver, with marked ascites, in which after several tappings he finally resorted to permanent drainage. A rubber canula was left permanently in place through an opening in the median line between the umbilicus and symphisis pubis, in one case for nine weeks, and in the other for seven weeks. The patients, who had been great sufferers from dyspnœa, loss of appetite, œdema, constipation, cardiac weakness, purpura, etc., were much relieved, and were enabled to live a comfortable existence. There was no return of the ascites after removal of the tube. The disease of the liver, of course, remained, and the patients finally died, in one death taking place suddenly, probably from heart failure, but an autopsy was not allowed. In the other case the autopsy revealed cirrhosis of the liver and fatty degeneration of the heart. There was no peritonitis. In the second case the drainage had been conducted to a bucket through a rubber tube connected with the canula. In neither case did inconvenience result from the procedure, except that in one eczema existed for a few days under the dressing about the abdominal opening. Dr. Caillé thought there was less danger of peritonitis from such an operation in ascites than there would be under ordinary circumstances. So far as the experience went, he thought the operation was one worthy of repetition in similar cases.

The President had seen some cases in which a spontaneous rupture had taken place from overdistension in ascites. It usually occurred at the umbilicus. He thought it was preferable to operate, and choose the place for making an opening. He related a case in which permanent drainage was made after having commenced an operation for an ovarian cyst. The mistake in diagnosis had been made from the fact that peritoneal adhesions had limited the extent of the ascites. A glass drainage-tube was left in the abdominal opening six weeks, and the patient was much relieved. He had heard since she left the hospital that there had been a return of the ascites. She would probably finally die of tubercular peritonitis. Since learning of Dr. Caillé's operation he had resorted to it in one case of cirrhosis of the liver with ascites, and it was followed by relief of the distressing symptoms; but the patient had been in a dying condition for some time, and he expired a few weeks after permanent drainage had been established. The President recommended small doses of bichloride of mercury long continued for interstitial inflammations in the liver, kidneys, brain, etc.

THE BALTIMORE ACADEMY OF MEDICINE.

Stated meeting held February 16, 1886.

Raynod's Disease (?)

Dr. A. B. Arnold related an interesting case that had recently come under his notice; it occurred in a man, a stoker on a steamboat. The patient presented the following lesions: From the first finger of his right hand the last two phalanges had disappeared, and from the ring finger of the same hand the last phalanx had dropped off. On the left hand the last phalanx of the thumb was gone, and the last phalanx of the little finger had loosened preparatory to spontaneous amputation. He considered this a case identical with three described by Raynod, all of whose cases occurred in men following the same occupation (stokers), and all having lost portions of their fingers in manner similar to Dr. Arnold's man.

The pathology of the affection is very ob-

scure. The patients complain of no pain whatever, and as a rule are in a tolerably good general condition.

Around about the stump in Dr. Arnold's case everything was perfectly normal, not so much as a dry eczema being present. The only other lesion that he could detect on the man's body, was an ugly excoriation in the palm of the left hand, which he did not think bore any relation to the special condition referred to.

He had seen another case with a similar loss of portions of the fingers, but the condition about the stump suggested elephantiasis.

Dr. J. Edwin Michael said he thought he had seen the same case, as the man had been making the rounds of the different hospitals in the city. It was his impression that the same case had been reported some time since in the *Journal of Cutaneous and Venereal Diseases* by Dr. Robert B. Morison, of this city. He said when he saw him that the lesion in the palm of the left hand, to which Dr. Arnold had referred, communicated with a sinus which ran for some distance up the forearm, and from which pus could be squeezed, but when the patient left the hospital the palmar wound had entirely healed.

Dr. J. J. Chisolm had seen one of these cases some years since, but took it to be elephantiasis.

Dr. Michael agreed with Dr. Arnold in not thinking it of syphilitic origin.

Dr. Arnold said in answer to Dr. Chisolm's question: "How does it differ from leprosy?" that there is no anæsthesia, no false œdema, etc.

Dr. Henry M. Wilson wished to know if leprosy was not on the increase in this country.

Dr. Arnold said that recently several cases of true tuberculous, anæsthetic leprosy had been imported into this country, and had been reported.

Dr. J. J. Chisolm said he recalled five cases of true tuberculous leprosy, two of which occurred in persons with whom he was personally acquainted. These cases he had seen while engaged in the practice of medicine in South Carolina. They occurred in natives, whose parents were also born in this country. They all occurred in white males.

Dr. J. Edwin Michael referred to a case reported by Dr. I. E. Atkinson, which existed and had its origin in Baltimore City. It was in a white woman. This too was true tuberculous leprosy.

Dr. Frank Donaldson, Jr., then read his admission thesis, entitled

Diaphragmatic Pleurisy.

It will be published in the April number of the *International Journal of Medical Sciences.*

Urethan.

Dr. John N. Uhler called the attention of the Academy to the new hypnotic, urethan. He gets most favorable results from its use. It is not disagreeable of taste, causes pleasant refreshing sleep, and is devoid both of nauseating and bad after effects.

He gives it in doses ranging from five grains to twenty-five grains, fifteen grains being the average. He substitutes it very effectually for chloral, paraldehyde, and opium. He has not used it as an anodyne, but only as an hypnotic. Considers its effects intermediate between chloral and paraldehyde.

Dr. J. J. Chisolm referred to a case that illustrates the rapidity of restoration to sight after operation in cases of complete glaucoma. In this case vision was perfect after ten days.

Dr. Samuel Theobald referred to some interesting results he had recently obtained by the use of salicylate of sodium in iritis, occurring in patients with a history of inflammatory rheumatism.

Three weeks ago a young lady had called to see him—she had a most intense plastic iritis—pupil perfectly immovable. She had only perception of light, and could not count fingers at the ordinary distance. She was ordered sodium salicylate, and in a few days she obtained much relief. This salt was then withdrawn and iodide of iron ordered. She did well until the end of several days, when she reappeared complaining of the same trouble, which increased in intensity, until at the end of two days she was in same condition as originally. The salicylate was repeated, as well as the atropia drops locally, and mercurial inunctions to temples. Cathartics were ordered, and in *two days* she was so very much improved that vision equalled $\frac{20}{64}$, and the media sufficiently clear to permit satisfactory inspection of the optic disk.

He had had some glaucomatous tension, but this did not prevent his ordering atropia, nor interfere with the physiological and therapeutical action of the drug.

Dr. J. J. Chisolm has had some astonishing results in these cases from large doses of salicylate of sodium. In choroiditis he gets remarkable results from the use of pilocarpine. Two decided sweats give pronounced relief.

Dr. H. P. C. Wilson spoke of a case in which he was recently credited with being the cause of the death of one of his patients. The woman was from a malarious district,

much run down, etc. She came to him to be operated on for laceration of the cervix uteri.

After treating her with tonics, etc., until her general condition was improved, he decided to operate, and appointed the hour; shortly before the time arrived the patient was taken with colicky pains in the abdomen, consequent upon drinking a glass of milk. These pains were allayed by the ordinary measures, and she then insisted upon his proceeding with the operation.

Local anæsthesia was obtained by the use of cocaine, and the operation performed without accident. After completion of the operation the pains returned, and were allayed by hypodermic injections of morphia. She spent a very restless night, and when he visited her the next morning found her quite ill.

Later in the day an erysipelatous inflammation appeared in the skin of the external ear, and became so intense that the patient succumbed on the next day. There was nothing whatever wrong at seat of operation.

Periscope.

The Recognition of Mortified Bowel; Operations for the Relief of Strangulated Hernia.

Dr. Reuben A. Vance thus writes in the *Cleveland Med. Gazette* for February:

The medical practitioner who has been hastily summoned to operate upon a patient with strangulated hernia finds himself confronted with problems, the gravity of which can alone be appreciated by those who have frequently met them. The medical treatment to be adopted, the extent to which taxis should be employed, and the time it is prudent to delay operative interference when other measures have proved fruitless, are grave questions, upon the solution of which the life of the patient depends. The operation decided upon, the particular method to be employed and the manner of dealing with the stricture—with or without opening the sac—are matters of minor consequence, and affairs that should be settled in the mind of of every practitioner by a reference to sound surgical principles and the teachings of experience. There are questions connected with the condition of the parts strangulated that must be solved by the surgeon during the progress of the operation, about which much less is said in works on surgery than their importance warrants. These pertain to the vitality of the part that has been strangulated, and the duty of the surgeon in the premises. If the part is still living, it matters not how much damaged by compression, it should be returned at once into the abdomen; upon this step the patient's life depends. If the part is mortified and dead, to return it within the cavity of the belly is to insure the patient's destruction; if he is to have a chance for life, other measures must be adopted.

Again, the decision of the operator can but rarely be guided or aided by aught but the conditions revealed by his knife during the operation. The state of the patient and the history of the case may indicate the imminence of mortification of the bowel; in the end the appeal is to the senses of the surgeon, and upon the conclusion at which he then arrives will depend the fate of the patient.

Under these circumstances it behooves every man who may be placed in position to make such a momentous decision, to at least go to the task sustained by every aid that can be derived from the experience of those who themselves have been placed in this dilemma and compelled to act with such lights as they then possessed—whose records, next to personal experience, become the best guide for those forced to follow in their footsteps.

The history of the case may throw some light upon the state of the intestine. This is especially so in those cases in which the severity of the symptoms suddenly subsides without the rupture having been reduced. The pain is violent, the abdomen distended, and singultus and stercoraceous vomiting present; suddenly the patient's sufferings cease, and were it not for the cold extremities, flickering pulse and persistent tumor—but above all, the teachings of experience—the surgeon could not but acknowledge that all tangible appearances portended a change for the better. Yet almost invariably gangrene of the gut has taken place, and the fallacious evidences of improvement above noted are in reality its best clinical exponent. Certain almost as these signs are, when present, yet it comparatively seldom happens that the surgeon has their aid in

guiding him in the measures he must adopt; they form, but infrequently, a part of the history of cases submitted to operation. If present, the surgeon is reasonably sure of what he will find when he operates; they may be absent, and mortification yet exist. The patient's chance of life depends upon the surgeon's ability to recognize mortification of the bowels when he sees it, and his promptitude and skill in dealing with it when present.

It scarcely need be said that mere darkening in color of the bowel, effusion of fluid into the sac, or exudation of lymph about the stricture, are of no special significance in this connection, and bear in no way upon the presence or absence of mortification. It has been again and again repeated in manuals treating of hernia operations that a deep, purplish discoloration of the bowel and absence of circulation indicate mortification; that when these physical signs are present the surgeon should press upon the strictured part, and if the color remains unchanged when the finger is removed, the bowel is dead. It requires but little practical experience in dealing with these cases to appreciate the fallacious character of these signs; the gut may be fairly black from congestion, and yet alive; the color may remain unchanged under pressure, and still that fact have no bearing on the question of mortification, for a band of stricture, as yet unappreciated, may be the sole cause of the persistent hyperæmia.

It is quite different as regards certain other signs, especially when two or more of them are seen in conjunction. *If the bowel be dark and mottled with grayish spots, of contracted and shrivelled aspect, with a slight amount of discolored fluid surrounding the gut, and a cadaveric odor apparent when the sac is opened*, mortification is certainly present, and the return of the strictured part within the abdominal cavity dooms the patient to certain death. The surgeon's duty is to open the sphacelated gut, apply a poultice, and favor the relief of the obstructed bowel by a free discharge of the intestinal contents through the outlet thus formed. An artificial anus is thus established, and the patient, for a time, must be content with this deformity; fortunately it is a condition susceptible of relief, and the surgeon may ultimately free his patient of even this defect.

On Phimosis in Infancy.

Dr. Geoffrey Hett thus writes in the *Lancet*, February 27:

My excuse for submitting the following observations on this subject to the consideration of the profession is that my experience leads me to think that phimosis is a morbid condition which is not infrequently overlooked. Its persistence is the cause of much unnecessary suffering among children, and a neurotic habit is often induced which, in some instances, is never shaken off, but continues to exercise a prejudicial effect upon the usefulness and happiness of a considerable number of men during the whole of their lives. It would be advantageous if the following rule were adopted by all those taking charge of midwifery cases; to examine every male child within a few days of birth, and, if the prepuce cannot be retracted by the exertion of a moderate amount of force, to perform circumcision on or about the eighth day of life. The advocacy of such a rule will appear superfluous to many members of the profession, particularly to those who have had special opportunities of observing the diseases of children. That it is, however, not accepted, or, if theoretically accepted, not acted upon by numerous practitioners of midwifery, is sufficiently proved by the frequency with which it is necessary to perform the operation in later life. Complete retraction of the prepuce is necessary in order to prevent the retention under it of the secretion of the numerous sebaceous glands in the mucous membrane of the cervix and glans penis (glandulæ Tysonii). The accumulation of this sebaceous matter acting as a peripheral irritant through the internal pudic nerves, may and often does cause central mischief more or less grave according to the constitution or the child and the amount of local irritation. If the preputial opening be so small as to interfere with the easy passage of urine, the condition will be aggravated by some of this fluid being forced under the prepuce and increasing the congestion of the mucous membrane. The injury resulting from this cause may be productive of nothing more than slight peevishness of temper; but, on the other hand, may give rise to convulsive attacks terminating fatally, and, of course, to any effect intermediate between these extremes. I feel sure that many an unfortunate little boy is credited with bad temper and punished for naughtiness whose irritability is due to neglected phimosis, and consequently entirely beyond his own control. There is also much reason for thinking that the habit of masturbation is frequently led up to by a morbidly excitable condition of the sexual organs due to the same cause.

Should no symptoms arise sufficiently severe to call attention to phimosis, and the child grow up to manhood with the defect unremedied, the liability to venereal disease must be largely enhanced by the impossibility of effectual ablution of the penis. The operation of circumcision is, in infancy, almost entirely free from risk if ordinary care be exercised. The only objection to it of which I am aware is the æsthetic one, and this cannot have much force in a clothes-wearing community, especially when the advantages derived from it are fully considered. Circumcision may be performed by seizing the extremity of the prepuce between the finger and thumb of the left hand, drawing it well forwards so that the outline of the glans can be clearly seen through the integument of the penis, and slicing it off diagonally downwards and forwards just in front of the glans with a sharp scalpel. The mucous membrane, which will be found still embracing the glans, should be spilt along the dorsum *quite up to the cervix*, turned back, and retained in position by a narrow strip of dry lint wrapped firmly three or four times round the penis. No sutures are necessary. The lint becomes saturated with blood, and, when this is dry, remains in position for from two to four days. On its removal the wound will generally be found completely healed, but, if any portion of it be granulating, it only requires the application of a little carbolized oil four or five times a day. I have never seen a case in which the dry lint failed to prevent any excessive hemorrhage. The eighth day of life is a suitable time for the operation, as the organism of the child has by then become accommodated to its new environment.

Epileptic Automatism.

Dr. Althaus reports this case in the *Brit. Med. Jour.*, February 27:

W. E., aged 23, single, a railway clerk, was admitted on October 2d, 1885. There was no inherited neurotic tendency. As a child, he suffered from convulsions during teething. At sixteen years, he was able to take a situation as railway clerk, and had his first fit, apparently without any appreciable cause, when seventeen years and three months old. There was an extraordinary variety about the fits, but the chief peculiarity had always been automatic action, either after an ordinary convulsive attack, or apparently even without one. Thus the patient, after having gone to bed seemingly quite well, would get up in the middle of the night, quite unconscious, and walk for hours about his bedroom. On one such occasion, he took hold of his watch, and kept winding it up until the mainspring broke, and continued the same movement of winding up for hours afterwards, until he recovered consciousness. When fits occurred in the day-time, he frequently came into collision with people, and hit or kicked them. If not interfered with in his movements, he did not give trouble; but if any one attempted to thwart him, he became violent, kicked, and plunged, so that it took five or six men to overpower him.

On one occasion, while sitting quietly in his office and writing, he was suddenly seen to assume a vacant look, and become insensible; he then pulled off his shoes and stockings, walked downstairs, and began to run about the station. The porters, who were acquainted with his peculiarity, were afraid to catch him; but a passenger, who threw some cold water over him, was knocked over, and told by the policeman that the patient must be let alone. A similar occurrence took place twice more on the same station, within a year and seven months. On another occasion, he wanted to pay a visit, but lost himself before arriving, and was noticed walking about the neighborhood, up and down, for about an hour and a half, being quite insensible; when he came to, he found himself with his eyes black, and lying on the pavement in a pool of blood. He had also "conscious fits," in which he behaved like a drunken man, and did outrageous things, feeling all the time utterly ashamed. In other fits, he fell down unconscious, and his whole body became rigid; he did not bite his tongue, but saliva kept running out of his mouth all the time. The urine had been expelled on only one single occasion. He was also subject to fits in which he was half conscious, and had a peculiar sensation of his tongue being tied; he could speak, but stammered unintelligible words, without any further symptoms. Occasionally the patient had an aura, when he suddenly felt a tingling in his feet, as if the legs went asleep; this sensation gradually proceeded upwards to the thighs, hips, abdomen, and chest, and when it reached his head he lost consciousness, and had a convulsive fit. Sometimes this aura lasted for a few minutes; at other times, however, it was instantaneous, shooting up from the feet into the head all at once. The greatest number of fits which the patient had had in a day was five, but he was rarely free from them for more than a week.

The patient had a good memory, and gave a very graphic account of his illness. He

had been discharged from his situation, not for any fault of his own, but because the fits upset the other people in the office, and caused constant disturbance. He wrote a good hand, but had a wild look and a strange expression. The face was covered with acne pustulosa, owing to previous treatment by bromide of potassium. The patient was at times subject to sneezing fits, which came on early in the morning, and lasted a considerable time. His functions in general were normal; but there were hypertrophy and dilatation of the left ventricle, the apex beating in the sixth intercostal space. There was, however, no murmur. There were no other symptoms. He was treated with a mixture containing borax, digitalis, and bromide of ammonium, with pills of zinc and henbane; and for the acne pustulosa of the face, with the ammoniated ointment of mercury. The result was very favorable, as the patient remained free from attacks during his stay in the hospital, which extended over three months, a few slight "vacant turns" in the beginning of the treatment excepted; and the acne of the face was readily cured.

Affections of the Rectum.

In all rectal affections, says Dr. John Chiene, in the *Edinburgh Med. Jour.*, there is often great depression of spirits. There is a close physiological connection between the genito-urinary tract and the rectum. Very frequently a patient will come to you complaining of irritability of the bladder, which may be due to some rectal irritation, *e. g.* piles or fissure; and it is, therefore, a good rule in all cases of irritable bladder to make a careful examination of the rectum, anus, and perineum. In all rectal examinations care must be taken to ascertain before making the examination that the patient is not suffering from acute syphilis. The discharge from an ulcer when the patient is in this state is infectious, and if there is any abrasion on the finger of the surgeon he may be inoculated during the examination. In an examination of the prostate it is best to place the patient on his back; but in an examination of the posterior rectal wall the patient is best lying on his left side. In the married female, the surgeon with two fingers introduced into the vagina can by pressure cause protrusion of the mucous membrane of the rectum, and in this way assist the diagnosis in cases of fissure and of internal piles. The best way, however, of examining a male patient is to make him lean over the back of a chair. If the buttocks are then separated, much may be learned by a visual inspection of the perineum. If there is any discharge, the skin of the perineum will be more or less excoriated, the area of excoriation corresponding to the portions of skin in apposition with each other. If there is a fissure, the opening of the anus will be firmly closed by the contraction of the sphincter, and the patient shrinks from any tactile examination. One small external pile is often an indication of the presence of a fissure at its base. A venous pile, due to the rupture of a small vessel at the junction of the skin and mucous membrane, will be indicated by a bluish colored projection at the seat of the rupture. A redundancy of the folds of skin around the anus indicates in all probability the presence of internal piles within the opening. A leathery appearance of the skin around the anus is seen in the affection termed pruritus ani. After a careful visual examination, the finger well oiled is to be introduced gently, and with a rotary movement, into the cavity of the rectum. In some rectal conditions associated with an abnormal dryness of the mucous membrane in the narrow part of the canal corresponding to the internal sphincter, this dryness will be best overcome by the injection of an ounce of warm oil before attempting to introduce the finger. After the finger is fairly within the rectum, inflammatory affections of the mucous membrane will be indicated by increased heat within the rectum. The presence of a fissure will be discovered as the finger is being introduced. Some fissures lie immediately within the opening. In this case the lower extremity of the fissure will be observed by forcibly separating the buttocks, and stretching the skin around the anus. In other cases the fissure lies altogether within the opening, and can only be diagnosed by feeling it with the finger. An anal speculum may be used in doubtful cases, but the educated finger is the best diagnostic. The condition of the prostate is carefully to be noted—(1) With regard to its size and its shape, increase in size of one or other of the lateral lobes indicating lateral hypertrophy of the gland. (2.) As to the presence of a soft point or points, indicating either inflammatory abscess or tubercular deposit in the process of disintegration.

In the examination of a fistula with a probe, the finger in the rectum will enable the surgeon to discover more easily the internal opening. In stricture of the rectum the stricture is almost always within reach of

the finger, and the condition of the stricture can be carefully examined. After the finger is removed, the presence of pus or slimy blood-stained mucus will indicate the existence of an ulcerated surface. Diarrhœa is often a symptom of stricture of the rectum, and in any one above middle age who suffers from persistent diarrhœa, a rectal examination should always be insisted upon in order to assist the diagnosis.

Fissure of the Anus.

In the *Edinburgh Med. Jour.*, for March, Dr. John Chienè tells us that the pain in fissure is of a twofold character; a sharp, cutting pain felt during movement of the bowels, and a throbbing, persistent uneasiness coming on after the bowels are moved, and lasting for a variable period. The primary pain is due to the stretching of the part. The persistent after-pain is due to spasmodic contractions of the sphincter. The base of the fissure consists of muscular tissue, and free division of this muscular base relieves the symptoms, gives the part rest, and allows the ulcer to heal. The injection of cocaine into the tissue forming the base of the ulcer renders the operation painless. The division of the base of the fissure, however, does not always give relief, and in a severe case of fissure it is more satisfactory to place the patient deeply under the influence of chloroform, to introduce the thumbs within the anus and forcibly to stretch the sphincter, dividing at the same time the base of the fissure. Introduce a morphia suppository after the operation, and prevent movement of the bowels for three or four days.

Division of the base of the fissure is very frequently done by introducing the finger into the anus, and then, with the finger as a guide to the upper extremity of the fissure, a sharp-pointed curved bistoury is introduced at the side of the anus and carried through the base of the fissure up to the point of the finger. This method of performing the operation is dangerous, and surgeons have been attacked with syphilis in consequence of pricking the finger with the point of the bistoury. The safer plan is to lay a straight blunt-pointed bistoury flat upon the finger, to introduce the finger with the bistoury in position, to feel for the upper extremity of the fissure, and then to turn the sharp edge of the bistoury towards the ulcer, the back of the bistoury lying on the finger. The knife is then carried through the base of the fissure by the pressure of the finger. The bistoury to be used, though probe-pointed, must have a cutting edge to its extremity.

Pilocarpine in Fish-poisoning.

Dr. K. Danilevsky, of Jeleznovodsk, Terskala Government, records, in the *Vratch*, No. 50, 1885, a case of poisoning by salt sturgeon, treated and cured by pilocarpine. The patient, a letter-carrier, began to vomit about four hours after eating. When first seen, on the next morning, he looked pale, haggard, extremely prostrated, his tongue and lips being quite dry, leathery (sole-like); saliva was entirely absent, in spite of the patient making incessant masticatory movements; the eyelids were swollen, and half-closed; the pupils were dilated. The abdomen was tense; the skin dry; the pulse weak, easily compressible, and slightly quickened; respiration, deglutition, and speech were embarrassed, in consequence of extreme dryness of the mucous membranes (in spite of constant drinking of water and milk); the urine and excrement were absent from the outset. On the third day all the symptoms decidedly grew worse, only a teaspoonful of highly concentrated urine being voided; the bowels were moved only after repeated enemata. During the fourth and fifth days, the prostration became dangerous, and there appeared intense anxiety, coldness of the limbs, and aphthous patches of the soft palate. At this stage, to alleviate the patient's subjective feelings, pilocarpine, a fourth of a grain a day, in a solution, was resorted to (only stimulants and warming bottles having been previously used). On the sixth day, a striking change followed. The patient became stronger, cheerful, able to speak loudly; the aphthæ disappeared; the saliva flowed freely; the pulse improved, the respiration became easy, and the daily amount of urine was increased. On the ninth day, the patient was able to sit up. The general weakness, however, lasted for another twelve days, the patient still looking "as if he were recovering from a prolonged severe disease." Dr. Danilevsky thinks that it is worth while to give pilocarpine a fair trial in cases of fish-poisoning.

—A note in the *Boston Medical Journal* says that a prominent Boston gynecologist has been sued for $10,000 damages by a pauper patient. She claims that he operated upon her against her will, and that the operation was unnecessary and improper, and she was discharged from the hospital at an unsuitable time.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

A WORD TO DELEGATES TO THE AMERICAN MEDICAL ASSOCIATION.

It is clearly apparent to all physicians who read medical journals—and we would ask what intelligent one does not?—that the coming meeting of the American Medical Association in St. Louis, is destined, beyond doubt, to be the most important one that has ever been held.

The meetings of this, as of all other medical societies, usually consist in the reading of a lot of papers, an interchange of friendly hospitality, and an adjournment.

But in May next there will be a meeting at St. Louis that is destined to go down into history as the most momentous gathering of medical men that has ever assembled in this country, for at this meeting the future policy of the International Medical Congress will be definitely settled. The controversy between the present committee, which is now making arrangements for the Congress under the direction of the Association, and those who object to the formation and work of this committee, will be brought to an issue.

Without animosity and prejudice on either side, we feel that we are imperatively called upon to say a few words on this very important question. It is of exceeding great importance, for upon the spirit in which the profession receives the final verdict of the Association, will rest the estimation in which we will be held, as sensible men or the reverse, by our European brethren.

All the talk that has been indulged in by those who are opposed to the Association in reference to the idea that it has not the right to control the Congress, which was at first their stock in trade, has been impliedly abandoned. It is now evident that their method of future warfare, their spring campaign, contemplates the passage by the Association of a resolution accepting the report of the present committee of arrangements, discharging them from all further service, and commencing the organization of the Congress *de novo*. Let us look into this question for a minute, and see just what the true position of affairs is.

The Association has, we maintain, the right to do just exactly that which it chooses, and when it has announced its decision, it then becomes the plain duty of all right-meaning medical men to uncomplainingly abide by this decision. The claim that the Association has not the right of arbitration, has been, we say, clearly abandoned by those who at first made this claim, as is evidenced by their determination to refer the matter in dispute to the Association for arbitration.

That they so intend was made plainly evident by the opposition in the recent meeting of the Philadelphia County Society, when a successful effort was made to substitute for the regularly nominated delegates to the Association a ticket made up of those who were known to be opposed to the present attitude of the Association and its committee. Therefore, since the opposition have seen fit to refer their battle-ground to St. Louis, we most emphatically say that they will stultify themselves, so to speak, if, when the Association has spoken, they do not, at once, cheerfully acquiesce and work manfully for the success of the Congress.

But we fear that such is not their intention; we very much fear that their programme contemplates the effort to capture the Association, and if they fail in this, then to organize a new association, from which it is possible that an invitation to hold an opposition Congress might go forth. That there is a movement on foot to organize a new national association, there can be no reasonable doubt, though this fact has been denied in our hearing by one of the organizers; at least, he denied that the purpose was to organize in opposition to the American Medical Association; but we ask how it would be possible to start a new national society that would not be in opposition to the present Association. Well, then, we say that the Association has the right to do what it pleases, and when it has so done, that we must give it our adherence.

The words that we wished to say to the delegates are to let them know that an effort will be made at the meeting in St. Louis to capture the Association by those who are not in accord with its present attitude. We wish to say that the war-cry of this army of conquest will be "Harmony;" "The good of the profession;" "The success of the Congress;" "The reconciliation of all differences in the profession;" and the like. We doubt not that the same measures will be resorted to that were adopted to capture the Philadelphia County Society, which we can only characterize as undignified, ungentlemanly, unconstitutional, and rebellious; rebellious because the manipulators succeeded, by means of a packed meeting (we use the word advisedly), in electing their list of delegates irregularly and in direct opposition to the provisions of the constitution and by-laws. We were present at this meeting, and know whereof we speak when we say that the majority of those men who voted for the irregularly substituted ticket were men who are rarely seen at the meetings of the Society, were young men, and, in very many instances, men who hold positions as clinical assistants to our professors, and whose heads, therefore, would have paid the penalty of that independence which they were too weak to exhibit.

It was a very significant fact that all the older men, that is those among them who evidence their interest in the Society by attending the meetings, voted for the regularly nominated list of delegates.

Now then, we have cautioned the delegates that a deliberate effort will be made to capture the Association by the methods usually employed to carry a ward convention; and we advise them strongly, that as they value the good name of the American profession, they should not tolerate any such proceedings, which they can prevent if they will attend the meeting.

To the Judicial Council of the Association, we have a word of the greatest importance to say: If the question comes before you, as it may, as to which set of delegates from the Philadelphia County Society are really the accredited delegates to the Association, your decision, if fairly rendered, must be in favor of the list that was nominated in the regular course that is laid down by the constitution, and not in favor of the list that was elected in direct violation of all law and precedent. If, perchance, the question arises, that although this ticket was nominated in due form, yet it was not elected, and therefore is not entitled to representation, it would seem that your duty was to deny representation entirely to the Philadelphia Society, a contingency that we would very much dislike to see; bnt nevertheless, you cannot conscientiously grant admission to this irregular delegation on any ground.

Again we would say to the delegates from all over the United States, be prepared to do your duty manfully at the next meeting. You will require all the courage you can summon to your aid that you may resist the great pressure that will be brought to bear upon you from both parties, and it will sorely try you to do that which your conscience tells you is the right thing. But be firm; go to St. Louis determined to carry out the instructions of your society, if they have directed you, at all hazards. If you are not instructed, then do the best you can; and above all, firmly make up your minds that whatever may be the decision of the Society, you will cheerfully abide by it, and with your whole heart and soul, do all to support and aid the American Medical Association.

Whatever may be the decision of this

tribunal, this journal will support it to the utmost extent of its ability.

WHAT ARE YOUR STUDENTS DOING?

To our readers who have sons or students attending lectures in this city, we would say that they are not doing what they ought to do. While we know that "boys will be boys," and that the young student from the country will see the "sights of the town," just as his now grave old father or preceptor did before him, yet we must call your attention to the fact that they are neglecting a very important part of their medical education. Let us premise by saying that Dr. Theophilus Parvin is one of the most charming and instructive clinical lecturers that we have in this country to-day. Well now, at a recent particularly valuable lecture of his, when he entered the room there were two students to greet him. This was not only insulting to the lecturer, but it demonstrated how poorly the average medical student appreciates what is required in a medical education. That which he hears in his didactic lectures he can read in his books; that which he *ought* to hear in clinical lectures, he can obtain nowhere else. Those of our readers who studied medicine at the University or the Jefferson twenty years ago, have no conception of the vast improvements in clinical teaching that have taken place within that period. Therefore we say to our readers, when you send your sons or students to Philadelphia to study medicine, do not fail to impress upon them the great importance of attending clinical lectures.

THE NATIONAL BOARD OF HEALTH.

Efforts are being now made in Washington to restore to the National Board of Health those powers of which it has been stripped, and which when it had them made it a very efficient body. We all know that to accomplish much good from a sanitary point of view we must have concerted action; we must have organization, harmoniously working, all the way from the National down to the County or Township or Village Board of Health. Duties that properly belong to the National Board of Health have been, for some occult reason, relegated to another department of the Government, and it is the effort to restore this power to its proper place to which we refer. For this praiseworthy effort we bespeak the influence of our readers, and ask them to urge upon their Congressmen the importance and justice of the measure.

NOTES AND COMMENTS.

The Disinfecting Influence of Watery Solutions of Carbolic Acid.

From the fact that sweet oil, to which carbolic acid has been added, is still employed in some hospitals and by some surgeons, we can only conclude that it is not yet generally known that a solution of the acid in oil is perfectly inert, and has no aseptic action whatever. If the oil seems to have done good nevertheless, it can only be explained by the oil having acted as a protective against the influence of the atmosphere; its frequent removal, and perhaps, also, the presence of the acid, having prevented the oil from becoming rancid. But it is in vain to expect any aseptic action, for carefully-made experiments have proven beyond the shadow of a doubt that none of the micro-organisms is impeded the least in its growth, development, and multiplication, by any amount of carbolic acid, if suspended or dissolved in *oil.*

About the strength which *watery* solutions should have to be effective, there also has been a great variety of opinion. To determine the question, Drs. Gärtner and Plagge, under Koch's guidance, have recently instituted a series of experiments at the German Imperial Board of Health—that institution from which all our knowledge of these things has emanated during the last decade. (*Arch. f. klin. Chir.*, xxxii., vol. ii., 85.)

These investigations were carried on with the utmost care to exclude all possible sources of error. It was first determined that any watery solution of carbolic acid, to be effective under all circumstances and under every condition, must contain three per cent. of the drug. It has been proven that this solution suffices to kill every micro-organism that may interest the surgeon, provided contact between the microbe and the disinfectant has been established as rapidly as possible after the supposed introduction of the bacteria or after exposure to the air. Amongst other facts that have been elicited by these researches may be mentioned the following: Washing for twenty seconds with this solution was found to free completely from bacteria the hair of a guinea pig, which, with a pure culture of these microbes, had previously been inoculated. All the experiments, further, were made with a "streaming fluid," that is, the watery solution of carbolic acid was applied by aid of an apparatus similar to a fountain syringe, so that a continuous flow of the fluid and a certain velocity of it could be maintained. This was done to prevent

the germs from again coming in contact with the skin. Regarding the knives used in these investigations and soiled by germs, all that was necessary was to let the steam of the three per cent. watery solution of carbolic acid once play over them, after which they were dried with a clean towel. They afterwards showed themselves completely free from bacteria.

We learn from these experiments that the only safe solution, if carbolic acid is used for the purposes of disinfection, is a three per cent. watery one. After a wound has been exposed to the stream of such a solution it should first be covered with an aseptic protection of rubber, etc., and over this the compress is applied, which is saturated with the same fluid, care being taken to prevent any admission of air, except through the disinfected bandages.

Fracture of the Larynx.

Dr. John B. Berry thus writes in the *Lancet:*

During the afternoon of February 6th I was called to see G. L.., aged twenty-one. He was reclining on a sofa, looking very pale. Extending from the tip of the chin to just above the hyoid bone was a superficial wound. The voice was like that of laryngitis. The prominence of the thyroid cartilage was gone. Placing my hand over the throat and requesting the patient to swallow, I detected unmistakable crepitus of the moving larynx. A more careful examination revealed what felt like a separation of the wings of the thyroid cartilage. The history of the accident was briefly this. About twenty minutes bofore I saw him he was working a circular saw, and was suddenly struck in the throat with great force by a large piece of wood coming from below upwards. For a few moments he had a hard struggle for breath, but managed to keep from falling by leaning against a bench. Water was brought to him, but he declined it, as he feared it would choke him. With the help of two men he walked home, a distance of about 500 yards from his work. Having applied a warm-water dressing to the throat, the patient was put to bed, his head and shoulders being raised. An hour later I saw the patient again in conjunction with Mr. Chaffers, whose help I sought when I saw the case was of such gravity. My diagnosis was confirmed, and seeing the patient was free from urgent symptoms, the breathing being quiet and full, and the condition of shock gradually passing off, we considered it best to continue the warm-water dressings and forbid anything being taken by the mouth except ice, leaving word that any change in the breathing should be immediately reported to us. About 1:30 next morning I was called up, as the patient was reported to be choking. After sleeping for about an hour and a half, during which time he breathed rather noisily, he woke up somewhat suddenly and at once began to struggle for breath. When I arrived he was unconscious, the eyes were open and fixed, the pupils dilated, the face pale, and the deep spasmodic efforts to breathe were failing. Having sent for Mr. Chaffers, I at once performed laryngotomy. Still no air seemed to enter, and no mucus escaped from the tube. Having satisfied myself the tube was clear and that no blood was obstructing the air-passages near the wound, I enlarged the opening and replaced the tube, with no better result, death taking place after a few more respiratory efforts had been made. Half an hour after death Mr. Chaffers and myself examined the larynx and trachea as well as we could through the operation wound. Besides the separation of the wings of the thyroid oblique, lines of fracture were made out on each side, through the wings themselves. Within easy reach of the finger, hanging down the trachea by a mere shred of fibrous tissue, was a part of the left wing of the thyroid cartilage itself, the size of a finger-nail, apparently the lower front angle; this was easily removed. I regret no post-mortem was allowed, as I am still in doubt whether to attribute the asphyxia entirely to the one piece of cartilage found, which was not wedged in the trachea, but simply lying flat against the anterior surface, but it may have acted like a valve during inspiratory efforts. During life, I may add, there was no spitting of blood, and after death perfectly white frothy mucus welled up from the throat.

Perforating Ulcer of the Stomach Opening into the Left Ventricle of the Heart, and Causing Death by Hemorrhage.

Before the Academy of Medicine in Ireland, January 15, Dr. Finny exhibited an extremely rare specimen of an oval ulcer (1 x ½ in.) of the stomach, situated on its anterior wall two and a half inches from the cardiac end, and two from the lesser curvature, leading up to and perforating the heart. The floor of the ulcer was the muscular structure of the under surface of the left ventricle, about one inch from the apex; and the ulcer, after perforating the stomach,

had eaten through the diaphragm and the pericardium. The stomach was adherent to the diaphragm round the ulcer, but the adhesions were very slight and of recent date. The pericardial sac had been obliterated by adhesive inflammation, and over the whole of the left ventricle the adhesions were very dense. Through the larger of several interstices between the exposed muscular tissue of the apex a probe could be passed upwards, and was found to enter the left ventricle behind a musculus papillaris attached to the posterior mitral curtain. The patient, a farm-laborer, aged 19, had died of syncope on December 5, 1885, preceded by the passage of blood from the bowels. There was no hæmatemesis. At the necropsy, the stomach and the whole intestinal canal were found full of liquid blood; the stomach alone contained two quarts. The source of the blood was the left ventricle, and it was probable that the blood escaped into the stomach, during both systole and diastole. The fatal steps in the pathological history of the case were:

1. Ulcer of the stomach of unknown duration.

2. Rheumatic pericarditis and adhesions of the left ventricle to the diaphragm, with obliteration of the sac.

3. Recent activity in the ulcer, perforating into the muscle of the heart.

The general muscular structure of the heart under the microscope was perfectly normal, and free from fatty degeneration, except the fibres at the floor of the perforation, which were granular and broken down, though free from all fat. This case was not unique, as there were three similar cases recorded in Vienna; the first by H. Chiari in 1880, the second by F. Brenner, and the third by Oser, in 1881.

Radical Cure of Hydrocele by Antiseptic Incision.

Dr. William T. Bull thus concludes a paper on this subject in the *N. Y. Med. Jour.*, March 13:

"The small percentage of failures after the antiseptic incision shows it to be, in my opinion, incontestably the *surest* way of curing any form of hydrocele; and, if we add to the operation the extirpation of the tunica vaginalis, the method would be absolutely free from any recurrence. But it is certainly not without risk. Even with its small percentage of deaths—.82 per cent.—it makes a wound of considerable extent, which exposes the patient to all the accidents of wound-healing; it necessitates, if one acts with due caution, longer confinement to bed, and demands rigorous attention to, and every facility for, antiseptic treatment. In view of these considerations, I shall be disposed in the future to reserve the operation for cases in which the injection method has failed, or to perform it only upon patients who, with knowledge of its chances, prefer to take them. As to the relative merits of the carbolic-acid and iodine injections, I have no opinion to express based on personal experience, but, from the experience of Weir, Keyes, and others, I should feel warranted in adopting the carbolic acid, and in sticking to it till it is proved less satisfactory than it seems to be at present. But I believe that the possibility of failure or of an *early recurrence* should never be left out of consideration in recommending the injection of either agent, and that we should be prepared with every antiseptic precaution to perform successfully the only truly radical operation—that of extirpation of the parietal tunica vaginalis."

Pemphigus of the Eyes.

Prof. Hermann Cohn describes in the *Breslauer aerzt. Ztsch.*, 1885, the only case of pemphigus of the conjunctiva which has occurred to him amongst 50,000 eye patients. He considers the disease exceedingly rare, probably more seldom met with than any other affection of the eye—a statement which explains the fact that some of the most experienced ophthalmologists have never seen a case.

The diagnosis of pemphigus of the conjunctiva can be made only when the skin also suffers at the same time from this exanthem. Should this skin disease not be present, the affection of the eye would be recognized as an ulcerative process of the conjunctiva, or what is more probable, as a croupous inflammation. For that is all the morbid lesion presented by the diseased conjunctiva, and its true character becomes known only on the appearance of the skin eruption. The prognosis in the majority of cases is very bad, and a treatment actually does not exist, every medication being in vain.

Whether the conjunctiva becomes affected in consequence of the general condition of the blood which gave rise to the pemphigus, or whether the virus is carried from a pemphighus blister to the eyes, is difficult to say, as several cases have been reported where but one eye suffered from the disease. If both eyes were invariably attacked the solution of the question would be found, but

there is one other point making matters still more doubtful; even if the skin disease ceases, in consequence of treatment or of the healing power of nature, the eye affection continues and is not influenced the least by the behavior of the exanthem on the skin.

Pilocarpin in Pneumonia.

The Paris correspondent of the *Brit. Med. Jour.* tells us that Dr. Humbert Mollière has successfully treated double pneumonia with pilocarpin; the patient, exhausted by dysentery and albuminuria, was attacked with pneumonia in both lungs, and the intestinal disturbance was greatly aggravated. A centigramme of pilocarpin was injected; the respiratory movements fell from forty-eight a minute to twenty-four, and dyspnœa was much relieved; four hours later, a fresh injection was made, and was repeated the next morning; each injection was followed by profuse sweats and salivation, and dyspnœa was greatly relieved. The patient rapidly recovered. In administering pilocarpin, M. Mollière was guided by former experience. An elderly man with uremia, accompanied with dyspnœa and delirium, who seemed dying, was greatly relieved, and ultimately cured by a similar treatment. Dr. Mollière describes another case. A young woman with a comatose form of uremia and renal lesion, following a cardiac affection, was freed from the comatose condition by injections of pilocarpin.

Trusses in Hernia.

As a rule, the wearing of a truss is regarded simply as a palliative expedient, hence it is well that we should be reminded by Dr. John Chiene (*Edinburgh Med. Jour.*, March,) that the application of a truss in the treatment of this common affection must not be looked upon as simply palliative. In old people with long-standing herniæ the curative action of a truss cannot be looked for; but in all recent cases at all ages a truss must be applied, not simply as a palliative, but in order to effect a cure. The younger the patient the greater is the probability of this good result. The hernial protrusion, after it has been once reduced, should never be allowed to come down again. Although in the recumbent posture the chances of the hernial protrusion occurring are diminished; still, as any exertion, as in the act of coughing, may during the night cause the protrusion, a truss should therefore be worn day and night. During the night less pressure is required to keep up the hernia, and if a spring truss is irksome to the patient the hernia may be kept up by a thick pad of layers of lint or layers of flannel, fixed in position by an elastic spica bandage.

Unusual Eruption in Scarlet Fever.

We should always be prepared for unusual signs in the eruptive fevers, hence we note from the *Brit. Med. Jour.*, February 27, 1886, that Mr. Richardson reports this case, which occurred in a boy aged five. The eruption appeared on the second day. It was confined to the anterior surface of the body, from the umbilicus to the upper fourth of the thighs; it was of a dark brownish purple color, not removed by pressure; the margin being sharply defined, studded with round flattish vesicles of a pearly-yellow color, largest in the centre of the abdomen, decreasing from one-sixth of an inch, and ceasing altogether about an inch from the margin. The fever was not great; temperature 99°. There was a slight blush on the fauces, and white tongue; no catarrh or enlarged glands. The vesicles gradually dried up, the purple color changed to brown, and the cuticle peeled off in large patches; the skin on the eighth day being smooth and pinkish, as after a blister. Desquamation of the rest of the body did not commence until after the eleventh, and was completed by the twenty-fourth day; the scales being small, except on the soles of the feet and palms of the hands. There were no renal symptoms.

Notes on Severe Endocarditis, with Special Reference to Cause and Treatment.

Before the Medical Society of London, Dr. A. E. Sansom read a paper on the above, giving notes of several cases of the disease, which he preferred to call severe or grave endocarditis, instead of malignant, a term which, he thought, tended to give rise to confusion. Under this head he included the aberrant forms of endocarditis, not being secondary to rheumatism, etc. The result of experiments on animals had been to prove that, although injections of the micrococci cultivations caused serious local and constitutional symptoms, they did not produce the vegetative or ulcerative endocarditis unless some artificial irritation of the valvular structures was resorted to simultaneously. In two cases of voluntary self-inoculation in healthy men, free from cardiac symptoms, the same result was obtained. Dr. Sansom hence was disposed to consider that the disease was due to the ravages of a micrococcus

acting on structures which had been or still were diseased. Hence the peculiar danger of septicæmia after childbirth, in women who suffered from valvular disease. The same thing applied to cases of osteo-myelitis, etc., under similar circumstances. He had used thirty-grain doses of sulpho-carbolate of sodium with marked success.

On the Combined Use of Cocaine and Nitrate of Silver in Certain Superficial Affections of the Eyes.

Before the Medical Society of London, Mr. Brudenell Carter read a short paper on this subject, to the effect that, while local applications of nitrate of silver were often of great service in congestive and ulcerative affections of the eye, it was generally quite undesirable and unnecessary to allow its action to spread beyond the particular areas; one of its effects being, he said, to strip off the corneal epithelium, when allowed to come into contact with it. It was generally somewhat difficult to limit this action, owing to the pain caused by its use, and the accelerated secretion of tears which ensued, and it was to mitigate these conditions that cocaine was so useful. By destroying sensation temporarily, it allowed the operator to apply his remedy with all the delicacy and certainty he could desire, and the lachrymal secretion did not increase so as to interfere with what he was doing.

Treatment of Acute Tonsillitis.

Dr. John Brown states in the *Brit. Med. Jour.*, February 6, 1886, that it is a rare event for suppuration to occur in acute tonsillitis, if treated early with the following mixture:

℞.	Sodæ salicyl.,	ʒ iss.
	Pot. bicarb.,	ʒ iss.
	Tinct. aconiti,	♏xl.
	Liq. opii sed.,	♏xxx.
	Sp. chlorof.,	ʒ ij.
	Aquæ ad.,	ʒ viij.

One ounce to be taken every two or three hours for the first thirty-six hours.

The same mixture is his sheet-anchor for rheumatic fever. He finds that the large doses prescribed in the London hospitals are not needed. Small doses, frequently repeated, are more effective, and almost free from the nauseating effects produced by large doses of salicylate of soda.

Renal Abscess: Nephrotomy.

Before the Glasgow Medical Society, Mr. H. E. Clark showed a patient with nephritic abscess. The ureters were catheterized by Dr. Newman, on December 23, 1885. His analysis showed the urine from the right kidney to be normal, but that from the left to be alkaline, albumen and pus being present in abundance. Nephrotomy was performed by Mr. Clark, on January 4, by an incision in the left loin; about one pint of pus was evacuated. Attention was specially called to the variations in the temperature, and in the amount of urine passed. The latter was as low as 14 ounces in twenty-four hours on one occasion, but since the operation it had gradually increased. There had been very little discharge from the wound, but there was considerable leakage of urine by it. In consequence of this, removal of the kidney was contemplated as soon as sufficient contraction had taken place.

Apparatus for Applying Heat and Cold.

In the *Brit. Med. Jour.*, February 27, Dr. Robertson describes an apparatus for applying heat and cold at any required temperature to the spine. It consisted of a long bag divided longitudinally into two compartments with inlet and outlet tubes, the former being attached to the tap at the bottom of a vsssel containing hot water, standing by the patient's bedside a little above the level of his body. The bag was being applied daily for three hours to the dorsal and lumbar regions of the spine, and water at the temperature of 130° was slowly circulating through it. The patient's illness was of about eighteen months' standing, and was regarded as chronic meningitis, with slight implication of the motor columns of the spinal cord. He was a man about 50 years of age. He said that he had experienced great relief from the pains and other unpleasant sensations in his limbs, since the bag was applied.

Meniere's Disease Treated by the Compressed Air-Bath.

Mr. J. Fletcher Little read notes of this case before a recent meeting of an English Medical Society. The patient, a professional man, suffered from syphilis before marriage. Since his marriage he had had several children, all of whom were free from specific taint. Menière's disease was diagnosed by a London aural surgeon in the spring of 1885, and anti-syphilitic remedies were ordered. Last autumn, deafness had much increased. The general health was very indifferent, and the spirits greatly depressed. The compressed air-bath, at one and a half atmospheres, was

tried, with immediate improvement. After two baths, the hearing had greatly improved, and the general health was better. An interval of six weeks had occurred without any return of the symptoms of Menière's disease. The patient was now taking iodide of sodium.

Hypertrophy of the Prostate.

If a patient says he has to rise at night to make water (says Dr. Chiene of Edinburgh), and that he makes water during the day with increased frequency, always be suspicious that he is not emptying his bladder completely. He makes only the overflow from a distended viscus. When there is a tendency to obstruction of the flow of the urine in consequence of hypertrophy of the prostate, there is little doubt that the occasional passage of a large-sized bougie is of value in keeping the channel patent.

Lead Poisoning.

To a recent meeting of the Glasgow Medical Society, Dr. Robertson described three cases of poisoning by lead. The patients were young women, from sixteen to twenty-two years of age. Two of them wrought in works for the dyeing of yarn, and prepared it for packing. Considerable quantities of fine dust were thrown off into the air in this process, and would seem to have been inhaled to some extent by the workers. Besides, their hands were constantly soiled by it. Both lead and arsenic were in the dyes, but the symptoms had been quite distinctive of the poisonous action of lead. One of the girls had severe general convulsions both before and after admission into the hospital. She was now, however, well and about to be dismissed. The other patient had suffered from severe mental disturbance, noisy delirium for the first three weeks, and, since, a certain amount of incoherence, which was still observable. It was anticipated that the mind would fully recover, but the girl was blind; and Dr. F. Fergus, who examined the eyes with the ophthalmoscope, had reported that there was marked atrophy of both optic discs. At first, she seemed to be quite deaf, but now hearing is partially restored. The third patient worked in a pottery, and appears to have had her system poisoned by a glaze containing lead used in her employment. The symptoms were entirely abdominal in this case; colic, constipation, vomiting, etc. She had well-nigh recovered.

Correspondence.

Useful Formulæ.

Eds. Med. and Surg. Reporter:

The following formulæ have been used by me for the past three years with uniformly successful results. In the chlorosis of young girls, in all forms of simple anæmia, in amenorrhœa due to anæmia, and in the nervous debility and neuralgias dependent on an anæmic condition, I have never seen a drug, or combination of drugs or chemicals, equal to those given below for rapidly increasing the number of red blood-globules, and bringing the roses to the cheeks of the pale and chlorotic:

℞.	Strychniæ sulphas,	gr. i.
	Sodæ arseniat.,	grs. v.
	Hydrarg. bichloridi,	grs. viij.
	Potassæ carb.,	
	Ferri sulph., āā	ʒij.

Fiat pil, No. cxx.

One pill for a dose 3 or 4 times a day after food.

Where the patient has an aversion for pills, as many have, particularly in such a quantity and for such a length of time, I prescribe as a substitute the following mixture:

℞.	Hydrarg. bichloridi,	grs. 1½.
	Sodæ arseniat.,	grs. iij.
	Strychniæ sulph.,	gr. j.
	Vini ferri amara,	fʒ xvj.

Take small tablespoonful in water after each meal.

Of course, existing errors of digestion must first be corrected, in order that the remedies may be assimilated, after which I can vouch for their efficacy. It will be observed that the pill formula is a modification of the justly celebrated Blaud's pill, but the additional ingredients certainly greatly improve on it. The mixture formula is modified from one in use containing liquor potassii arsenitis, and tincture of nux vomica, but on account of the varying strength and unreliability of these two preparations, the sulphate of strychnia and arseniate of soda were substituted with advantage. The bichloride of mercury in both formulæ, aside from its recognized efficiency in the conditions indicated, is valuable in counteracting the constipation produced by prolonged use of iron.

G. H. Kirwan, M. D.

Wilkes-Barre, Pa.

Coffee-eating Habit.

Eds. Med. and Surg. Reporter:

Instances of the coffee-eating habit may be common enough, but it has never been

my fortune to know of an instance before, and I do not remember to have seen any reported.

Miss E. M., white, aged 22 years, for four months has been eating the ordinary roasted but unground coffee berry. She began by using small quantities, for the purpose, as she alleges, of having something in her mouth to chew. A month ago she was consuming a half-pound of coffee a day, but latterly has reduced the amount on the urgent solicitation of her friends, to about one-fourth of a pound per day. She seems to feel the urgent demand for the coffee which an opium or chloral eater does for his favorite drug, and can do without it for a short time only without discomfort. After a few hours' abstinence, intense nervousness, trembling, and a strong appetite for the coffee makes itself manifest. The girl is employed to run a sewing machine in a shirt factory, and keeps a tin box of coffee near her while at work. She also keeps some near her bed at night.

Whether it is an instance of abnormal appetite, as with clay-eating, etc., or a habit dependent on the neurotic effect of the berry, may be questioned, for she has for a long time been accustomed to eating ashes. The coffee is not eaten continuously, but at intervals. The effect on her health has been bad, as with excess in coffee-drinking. Formerly she enjoyed excellent health, but since using the coffee she has become pale, sallow, and nervous. The pulse is weak and irregular, and the stomach deranged. There is considerable swelling of the ankles. She is not chlorotic. Dyspnœa is extremely marked on going up-stairs or climbing a hill.

The case was seen incidentally while attending another member of the same family, and is chiefly interesting from the large amount of coffee consumed, and the profound constitutional effects produced.

Rhus Poisoning.

Eds. Med. and Surg. Reporter:

About a year ago I had a case of serious poisoning in a very healthy man from coming in contact with swamp sumach (rhus toxicodendron), and, after weeks of terrible torment (this is the word), he apparently recovered.

The pruritus was such that to lie down in bed was utterly impossible.

Only a few days ago, after a cold ride, the peculiar eruption appeared upon the face and neck, but with symptoms much more mild than in the former attack.

Of course we conclude that the poison still lives in the system.

I would like very much to hear from some of the readers of this journal on this subject.

Any information with a view to cure will be most gratefully received by the writer and the patient. C. E. D.

Bedford, N. Y., January 27, 1886.

Shortening of the Round Ligaments.

Eds. Med. and Surg. Reporter:

In your issue of December 12, 1885, I reported a case of Alexander's operation as performed before his polyclinic class by Prof. Nancrede, on the 23d of the preceding October.

The lady was seen last week, and now, five months after operation, is completely cured of her prolapse, cystocele, and rectocele, with all their train of symptoms, with a great restoration of her health generally. There has been no drag whatever upon the shortened ligaments nor lines of incision. She continues the use of the Smith-Hodge pessary. A. B. Hirsh, M. D.

Remedy for Bee-stings.

Eds. Med. and Surg. Reporter:—

Having used Squibb's Cholera Mixture for the past year as a remedy for bee-stings, I can say it is a specific, instantaneous in its effect if applied within a few minutes after the stinging, preventing soreness and swelling. Yours truly,

E. Pratt, M. D.

Bellefontaine, Ohio.

News and Miscellany.

Planting of Fruit Trees.

E. P. Roe thus writes in *Harper's Magazine* for April:

If the acre has been enriched and ploughed twice deeply as I have already suggested, little more is necessary in planting than to excavate a hole large enough to receive the roots in their natural positions. Should no such thorough and general preparations have been made, or if the ground is hard, poor, and stony, the owner will find it to his advantage to dig a good-sized hole three or four feet across and two deep, filling in and around the tree with fine rich surface soil. If he can obtain some thoroughly decomposed compost or manure, for instance, as the scrapings of a barn-yard, or rich

black soil from an old pasture, to mix with the earth beneath and around the roots, the good effects will be seen speedily, but in no instance should raw manure from the stable, or anything that must decay before becoming plant food, be brought in contact with the roots. Again I repeat my caution against planting too deeply—one of the commonest and most fatal errors. Let the tree be set about as deeply as it stood before removal. If the tree be planted early in spring, as it should be, there will be moisture enough in the soil, but when planting is delayed until the ground has become rather dry and warm, a pail of water poured about its roots when the hole has been nearly filled will be beneficial. Now that the tree is planted, any kind of coarse manure spread to the depth of two or three inches on the surface as a mulch is very useful. Stake at once to protect against the winds. Do not make the common mistake of planting too closely. Observe the area shaded by fully-grown trees, and you will learn the folly of crowding. Moreover, dense shade about the house is not desirable. There should be space for plenty of air and sunshine. The fruit from one well-developed tree will often more than supply a family, for ten or fifteen barrels of apples is not an unusual yield. The standard apples should be thirty feet apart. Pears, the dwarfer growing cherries, plums, etc., can be grown in the intervening spaces. In ordering from the nurserses, insist on straight, shapely, and young trees, say three years from the bud. Many trees that are sent out are small enough, but they are old and stunted. Also require that there should be an abundance of fibrous and unmutilated roots.

Gonorrhœal Infection from Baths.

The *National Druggist* says:

Attention is called in some of the medical journals to the danger of infection with gonorrhœal virus, and the consequent development of that disease, from using the same bath which has been used by some diseased person. A case of a girl-child is quoted, who contracted gonorrhœa in this manner from her mother, to whom the disease had been imparted by her husband. Especial attention is called to the condition of public baths in winter, in which large and mixed crowds bathe, and in which the water is comparatively seldom changed, on account of the expense of heating it.

While we suppose that this may account for the disease in children bathed in the tub in a bath-room, we warn our more mature readers that the "bath racket" will be considered "too thin" by their physicians, and, together with the water-closet explanation, will be relegated to the realms of fiction; to the "what might have been," but not "what was." Not every adult will be credited with the saintly simplicity of the gentleman who once consulted the writer after three years of married life, because no children came to bless their union. Inquiry developed the fact that his wife was still a virgin, the husband having the idea that he had done his share by going through the marriage ceremony in the church, and the Lord would provide the children; forgetting, that the Lord only helps those who help themselves. The majority of adults, if suffering from gonorrhœa, will be credited with having come by it *ad legem artis*, and not by any very improbable "bath" communication. Cleanliness is to be be lauded, of course, and filthy public baths will only be of benefit to those who are themselves still more filthy; but we doubt whether gonorrhœa is one of the dangers to be dreaded from such homœopathic attenuation of the virus.

Galvanized Corpses.

The *Chemist and Druggist* says:

"Cremation and inhumation are not the only resources of civilization in regard to corpses. M. Kergovatz, chemical engineer of Guiparas (Finisterre), has advocated in the Paris *Figaro* a galvanoplastic treatment which, he declares, he has proved to be practical. He rubs the body with plumbago, and then plunges it in a bath of copper, zinc, silver, or gold, according to the funds, available, and he thus obtains a statue which cannot fail to be an accurate likeness, and which, he thinks, would be in all respects superior to the ordinary representations of great men in our streets. Besides, the actual person of the dead is retained. He declares his intention of submitting his invention to the Municipal Council of Paris." Burying, he says, has been condemned by experience; cremation destroys all evidence of crime in cases of murder, and embalming is expensive.

The Difficulties a Physician has to Combat.

The *Med. Summary* very truly says that the physician is often censured because he fails to cure his patient. People appear to think that he carries in his head a remedy for all ills, and should he make an error in his diagnosis or fail to give instant relief,

they discharge him and engage another, who in many instances does no better. The ignorant laity know no better, but the educated should not join in this abuse, for they do know better.

Medicine *is not* an *exact* science, neither is therapeuties. We know morphia induces sleep, but cannot tell *how*, nor can we tell whether the patient is a proper one for it to act upon. We know that many drugs produce certain effects, but we cannot tell whether our patient can take them with advantage. Our only plan is to try, and if we fail, try again. The man knowing these facts who condemns a physician only shows ignorance, bad temper, and is unworthy of our respect. Physicians, as a class, are honorable, unselfish men, and great respect should be shown them because of their honorable calling, years of study, and devotion to humanity.

Ice in the Sick-room.

A correspondent of the *National Druggist* thus writes:

The writer's son suffered with typhoid fever during the heated term of last summer, when the temperature of the room often rose to 90° or 95°, and the patient's temperature ran up to 105° F. and over.

A number of tubs were placed in the room and kept filled with ice, and the doors kept closed. The temperature of the room sank to 80° or less, an average of 12° or 15° below the temperature of the other rooms in the house, and the cooler atmosphere not only added to the comfort of the patient, but aided in keeping down the body-temperature, and materially contributed to a final recovery.

We would strongly urge the use of ice in the room as a measure of comfort and luxury for all who are confined to their beds during hot summer days, if they can afford the expense, which, if ice for cooling purposes is taken, is very moderate—the cost last summer being only 15 cents per 100 pounds, and the average consumption somewhat less than 1,000 pounds a day.

The Proper Weight of Man.

Prof. Huxley asserts that the proper weight of man is 154 pounds, made up as follows: Muscles and their appurtenances, sixty-eight pounds; skeleton, twenty-four pounds; skin, ten and one-half pounds; fat, twenty-eight pounds; brain, three pounds; thoracic viscera, three and one-half pounds; abdominal viscera, eleven pounds; blood which would drain from the body, seven pounds. The heart of such a man should beat seventy-five times a minute, and he should breathe fifteen times a minute. In twenty-four hours he would vitiate 1,750 cubic feet of pure air to the extent of 1 per cent. A man, therefore, of the weight mentioned, should have 800 cubic feet of well ventilated space. He would throw off by the skin eighteen ounces of water, 300 grains of solid matter, and 400 grains of carbonic acid, every twenty-four hours; and his total loss during that period would be six pounds of water and a little more than two pounds of other matter.

Revoking Regulations Issued October 10, 1885, for the Maintenance of Quarantine Inspections on the Northern Frontier of the United States.

The following circular has been issued from the Treasury Department to the medical officers of the Marine Hospital Service, Customs officers, and others concerned:

"Official information having been received that the small-pox, which recently prevailed as an epidemic in certain provinces of the Dominion of Canada, is now under control; therefore the regulations issued October 10, 1885, for the maintenance of quarantine inspections on the northern frontier of the United States, are hereby revoked."

A Justice's First Charge.

He said: "Gentlemen of the jury, charging a jury is a new business to me, as this is my first case. You have heard all the evidence, as well as myself; you have also heard what the learned counsel have said. If you believe what the counsel for the plaintiff has told you, your verdict will be for the plaintiff; but if, on the other hand, you believe what the defendant's counsel has told you, then you will give a verdict for the defendant; but if you are like me, and don't believe what either of them have said, then I'll be d——d if I know what you will do. Constable, take charge of the jury."

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE THREE WEEKS ENDED MARCH 13, 1886.

Benson, J. A., passed assistant surgeon. Resignation accepted, to take effect April 6, 1886, and leave of absence granted until that time, March 10, 1886.

Personal.

—Dr. F. E. Stewart, formerly one of the editors of that excellent journal, *The Therapeutic Gazette*, has been appointed Demonstrator of Pharmacy in the Woman's Medical College of Philadelphia.

Items.

—The resignation is announced, after twenty-five years' service, of Dr. Baranowski, Professor of Therapeutics and Medical Diagnosis in the University of Warsaw.

—Herr v. Gossler, medicinal rath, has announced that from next summer students in Prussian universities must undergo instruction in vaccination with animal lymph.

—"Excuse me, sir," said a brakeman at Rahway, N. J., as a passenger was about to board the train, "but how far do you go?"

"New York."

"Take the next car back. This car is reserved for Paris passengers."

—Dr. V. Teyxeira reports in the *Gazzetta degli Ospitali* that a woman in the seventh month of pregnancy was delivered of five living children—two females and three males. Three had died, and two seemed in a hopeless state at the date of report. The mother was progressing fairly.

—Dr. Gurfinkel writes, in the *Vratch*, No. 46, 1885, that recently he came across an extremely rare case of helminthiasis (in a peasant), in which a dose of decoction of pomegranate root expelled one hundred and two *arshins* (= 238 feet, 1 *arshin* = 2⅓ English feet) of tapeworms, twelve distinct heads being found in the mass.

—Several soldiers in different French regiments have been bitten by mad dogs. M. Pasteur has consented to treat them, without payment. Some wards in the military hospital, the Val-de-Grace, have been prepared, in order to receive patients menaced with hydrophobia. Madame Dagnan has bequeathed 6,000 francs for the benefit of M. Pasteur's patients.

—Mose Billups, a country darkey, entered Kiser's drug store and inquired:

"Boss, yer got any smoothing syrup?"

Kiser gave him a bottle of Mrs. Winslow's celebrated compound, and inquired "if he wanted anything else."

The darkey looked around, and seemed to be in deep meditation, when he broke out with:

"Yas, my old woman tole me ter git her some er dem confounded liber-coated pills and er box er consecrated lie—yer got eny er dat?"

—The secretary of one of the New York schools for practitioners lately received a letter in which the writer said: "I have practiced over twelve years—and wish to know if you will issue me a Diploma if regular fee be paid, without actual attendance. Would like to have one before going to ——. Please let me know by return mail and confer favor. . . . P. S. Have a well preserved 'fœtus' you can have if of any benefit, as I do not wish to take along."

—"Yes, I'm in the lecture business," said the long-haired passenger, "and I'm making money. I've got a scheme, I have, and it works to a charm. Big houses wherever I go."

"A scheme?"

"Yes. I always advertise that my lectures are specially for women under thirty years of age, and for men who are out of debt. You just ought to see the way the people come trooping in."

—Dr. Forster, of Amsterdam, contributes an article on "How Shall Physicians Cleanse their Hands?" to the *Central. für Klin. Medicin*, and has, after a series of careful experiments, come to the conclusion that a solution of carbolic acid of the strength of two and a half per cent. was not capable of "sterilizing" the fingers after visiting infectious patients, but that a solution of corrosive sublimate of the strength of one in two thousand formed a reliable antiseptic wash.

—There were, according to Dr. Dujardin-Beaumetz, nineteen deaths from hydrophobia in Paris last year—a number higher than in previous years; and yet the number of stray dogs destroyed was also higher—viz., 5,060. Of these nineteen persons, fifteen were males and four females. The time of incubation varied from nineteen months (in the case of a young man of twenty-six) to twenty-nine days (a child of eleven). In only one case was the time of the bite unknown. Excluding that, and the exceptional case of nineteen months, an average of about two months is arrived at for the time of incubation. As to duration of the disease, the extreme limits were one day and eight days; average, three and a half days. In no case were the lower limbs bitten.

OBITUARY NOTICE.

MRS. DR. H. KNAPP.

The wife of Dr. H. Knapp died last month after a short illness at the home of her parents, in Germany. Dr. K. and family are all abroad, and will return in May.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*

2d. *All materials weighed with scrupulous exactness.*

3d. *The mass sufficiently consistent to maintain the globular form, and yet readily soluble in the stomach.*

4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

RIDGE'S FOOD

FOR INFANTS AND INVALIDS.

Cereal foods are regarded by some with disfavor, as diets for infants, especially by those who maintain the dictum of chemistry in the matter as conclusive. It is urged that as they usually contain a certain amount of unconverted starch, this ingredient, owing to the absence from a baby's saliva of the solvent "*ptyalin,*" must cause indigestion and irritation in its passage through the stomach and intestines. Yet Bouchardat and Sandras have demonstrated that starch, given to animals in excess of what the saliva can act upon, has its coherencies eroded, dissolved, and transformed into sugar, when it meets the pancreatic fluid in the duodenum. The inference is that the conversion of starch is not wholly dependent on the secretions of the buccal cavity, and that the presence of a limited quantity in an infant's food is not necessarily a source of disorder. Moreover, in dietetic questions the verdict of chemistry can only be received *cum grano salis*; and the final appeal is to practical experience; what might, could, would, or should be, under supposed conditions, loses much of its practical value, when we have easy access to what is.

The preëminent popularity of Ridge's Food has caused it to be singled out for special criticism and attack, and unsparing denunciations have been hurled at it by and on behalf of unsuccessful rivals, whose professed zeal for the welfare and protection of the innocent public would be really touching, if it did not employ the language of disappointment and defeat. Our appeal to the public for its patronage has rested on the excellence of our product; and its full justification is found at this time in an experience of thirty years, during which the sales of Ridge's Food, throughout Great Britain and her Colonies, as well as in every State in the Union, have steadily and largely increased.

Ridge's Food is made from carefully selected winter wheat which, having been reduced to an almost uniform fineness, is thoroughly cooked by a steam baking process. The nitrogenous and phosphatic elements, in which wheat is so rich, are carefully preserved, and a large proportion of the starch is converted into dextrine, while the residue undergoes a further change when the food is prepared, as directed, in the nursery, producing an article of diet at once abundantly nutritious and easily digested. Samples of the preparation will be found alittle sweet and slightly alkaline.

It is claimed for Ridge's Food that it is acceptable to the most irritable stomach of infant or invalid, when used (as sometimes it must be) without milk; and that then it is alone sufficiently nutritive to sustain life.

It is also affirmed that the objections urged against the use of cereal foods in no way or degree apply to our preparation; that the consequences predicted as following such a diet for infants never occur where Ridges Food is used. So contrary, indeed, is the prediction to the results of experience, that an eminent firm of druggists in Chicago, who for many years have sold largely of our preparation write: "Its soothing and satisfying properties are so marked, as often to cause customers to inquire *it does not contain some opiate?*"

We shall be pleased to forward a sample of RIDGE'S FOOD to any physician not yet acquainted with it, who may favor us with their address, satisfied that, with a fair trial, we shall secure his commendation.

ERYSIPELAS FOLLOWING INJURY TO THE BUTTOCK; HEREDITARY SYPHILIS IN A BOY OF SEVEN; PISTOL-SHOT WOUND OF ABDOMEN; AMPUTATION OF ARM.*

BY JOHN H. PACKARD, M. D.,

Of Philadelphia.

The patient, a man aged fifty, some four or five days since had a fall, resulting in what resembles an erysipelatous inflammation of the buttock. The whole part is covered with the color peculiar to erysipelas, and when I pass my finger across the skin it leaves a white mark which remains some time. The same thing is seen in scarlet fever, while in ordinary inflammation this would not occur; therefore, we consider it a valuable aid in diagnosis, for there must be some deteriorated constitutional condition, as is the case in a scarlet fever patient. Upon careful examination of the part, I am able to elicit fluctuation; there must be pus contained within the swollen inflamed area.

In examining for fluctuation, it is well to remember that unless we feel in a line with the muscle we may fall into errors of diagnosis. As in all cases of suspected erysipelas, this man was placed on diet treatment, *i. e.*, nourishing food, quinine, and rest.

Knowing there is pus, I do not hesitate to make an incision. It will be a short, but painful operation. I will therefore give him ether, but only to the point where his upraised arm falls involuntarily to his side. At this point there is a moment of complete anæsthesia when the knife may be used without the patient's knowledge; it must, however, be used rapidly, for within fifteen seconds he is wide awake again.

It is of value to bear this point in mind, for it is most useful in office practice, where patients may desire to return immediately to their homes or occupations.

When anæsthesia is complete, it often is twenty-four hours before the effect passes off, or at least till the patient feels well.

HEREDITARY SYPHILIS IN A BOY OF SEVEN.

Here is a small boy of seven years, whom I show with much pleasure, as the case is instructive, being such as might mislead the young practitioner. Two weeks ago this child had a punctured wound of the forefinger at the first phalanx. Look at it now, and look well at the little patient. Why this peculiar swelling following so slight an injury? The swelling is a typical one in this class of children. It extends from the first to the second joint of the finger, and is greatest at a point midway between the joints. The patient, even for a child of seven, is not robust. The cervical glands are enlarged. The cornea is not opaque, but the expression of the eye is dull, lustreless. In examining his teeth (which of course are temporary), I note that they are worn down and smooth. When these are replaced by permanent teeth, they will be notched, known as *Hutchinson's teeth.*

This child has *hereditary syphilis*, and this is manifested in the peculiar swelling of the finger. This is *never* seen following such a wound in a healthy child.

It is important to bear in mind this diag-

* Abstract of clinical lecture delivered at the Pennsylvania Hospital.

nostic point, for no amount of local treatment would ever heal this finger, which is merely a local manifestation of a constitutional taint.

The little patient will be put on anti-syphilitic treatment, when the swelling will disappear and the finger resume its normal shape.

PISTOL-SHOT WOUND OF ABDOMEN.

This man was brought into the hospital one week ago, having been wounded in the abdomen by a pistol-shot. At first we were in doubt that the kidney was involved; however, after being admitted, the urine drawn off was perfectly clear, which of course would not be the case if that organ had been wounded. There was some threatening of peritonitis, and we therefore applied eight or ten leeches in the region where these symptoms existed, and the usual treatment. We quieted the movements of the intestines with opium in the form of suppositories, and did not relieve the constipation till after nine days, when he had a natural movement. All symptoms of inflammation subsided, and he presents to-day a well man.

This case seems to illustrate how near we may be to having severe injury, and yet with careful preventive treatment make a free escape. On the other hand, had we been in haste to effect a movement of the bowels in this patient's case, he would doubtless have suffered the greatest trouble, or mayhap have lost his life. N. B.—"Prevention is better than cure."

AMPUTATION OF ARM.

This young man was, one week ago, admitted to the hospital, having had his arm caught between the buffers of freight cars, just above the elbow-joint. The bone escaped injury, but not so the brachial artery, which was felt distinctly pulsating at the wrist.

The only thing to be done was ligature of the artery above the injury, to anticipate secondary hemorrhage, which would undoubtedly have been fatal; but as a result of cutting off the blood-supply, the arm became cold and bloodless, while a dusky flush spread almost to the shoulder. The whole case looked extremely unfavorable, and the patient wisely consented to amputation as his only remaining chance for life.

On the day of the operation his temperature was 104⅘°, the next day it fell to 101½°, and on the day following to 100°, since which time it has been normal.

To-day we redress the stump, which has not been uncovered in three days; some odor is perceptible, but it is not due to putrefaction, except of the discharges. There is neither swelling, nor sloughing, the stump is in good condition, and we wash it with a solution composed of—

R.	Ac. carbolici,	gtt. xv.
	Tinct. iodini,	gtt. xv.
	Aquæ,	Oj.

Which is an excellent antiseptic wash.

Communications.

NOTES OF A CASE OF NECROSIS OF THE VOMER.

BY ALEXANDER W. MacCOY, M. D.,

Of Philadelphia, Pa.,

Member of Philadelphia Laryngological Society, etc.

During the latter part of July, '85, a gentleman, a resident of Maryland, consulted me for relief from a profuse and troublesome nasal discharge, which constantly escaped from the nasal chambers anteriorly and posteriorly. The discharge was muco-purulent, with some slight odor. The gentleman was of remarkably fine physique, apparently in perfect health. His history was as follows: Several attacks of nasal discharge had occurred prior to the one he now suffered from; the first attack began two years before, and was quite similar to the present attack. His family physician in Baltimore gave him treatment which checked the discharge; but about one year later the discharge began to annoy him again, and showed all the characteristics of the first attack. Treatment again relieved him, but during the spring of '85 the nasal discharge returned, when the usual treatment failing to cure him, he was referred to me.

Some years before any of these attacks of nasal discharge, he had consulted several surgeons for a peculiar ulcerating wart on the right cheek, close to the side of the nose and one inch below the inner angle of the right eye. A prominent surgeon in this city, whom he consulted, advised him to have it cut out, hinting to him that it was probably an epithelioma; his physician in Baltimore applied a caustic to it, and it healed, leaving an irregular puckered scar. Many years before this sore appeared, he had had a peculiar-looking wart on the palmar surface of the right hand at the base of the index finger, which disappeared, leaving a scar which is still faintly visible. He also acknowledged having had a sore on penis at 18 years of age, which was cured under the treatment of a famous French surgeon in Paris. No other symptoms whatever had

showed themselves except those above mentioned.

Examination of the nasal cavities anteriorly showed nothing excepting a rather highly colored membrane, slightly swollen on the right side. Inspection with the rhinoscopic mirror posteriorly showed a profuse thick discharge of a greenish-yellow color adhering to the vault of the pharynx, and filling up the nasal openings, especially the right one. After the mucous membrane of the vault had been cleansed with much difficulty, the mucous membrane of the free edge of the vomer and of the nasal openings was found to be highly red and swollen. At the vault, to the right of and above the Eustachian tube, a long, narrow ulcer, of irregular edges and granular base, bathed in pus, was seen. The right opening appeared more swollen than the left, markedly noticed over the posterior portion of the middle turbinated body; the free edge of the vomer was swollen, reddened, and irregular, having lost its normal outline. A probe passed along the right nostril from the front disclosed, far back in the nostril, a roughened surface over the septal wall, similar to dead bone. Quite a large surface was bare and roughened. The probe passed in the left nostril showed necrosed bone also over the septal wall. The most diligent search with the probe failed to discover any other bony tissue necrosed. The diagnosis was inferentially made: specific necrosis of the vomer. The ulcer at the vault was undoubtedly specific also. The usual treatment was instituted, with the most satisfactory results. The necrosed vomer came away almost in its entirety, discharging through the naso-pharynx into the mouth; the ulcer rapidly healed, and the secretion gradually subsided; the opening in the septal wall appeared to grow smaller. The mucous membrane covering the free edge of the vomer, after the necrosed bone was exfoliated, appeared to settle down and form an elbow, but later this appearance was not visible. To-day the rhinoscopic image posteriorly shows all of the tissues normal, no evidence being visible of an opening having been made in the septum at any time; nor could the perforation of the septum be seen anteriorly, the opening in the septum being only determined by the probe. The case is instructive as showing how obscure the real cause of a nasal discharge may be, without exact and thorough examination of the nasal chambers; and how syphilis often plays a much more important rôle in certain cases of rhinitis than we are willing to acknowledge.

LANOLIN: ITS USE IN THE TREATMENT OF DISEASES OF THE SKIN.

BY JOHN V. SHOEMAKER, A. M., M. D.,

Of Philadelphia.

My attention was attracted not long since to an able and exhaustive address delivered by Prof. Oscar Liebreich, on lanolin as a new basis for ointments. The investigations of this eminent chemist and physician clearly showed that he had produced a cholesterine fat far superior in its action on the skin to either glycerine fats or mineral oils. In the course of his investigations with this substance, in showing its great absorptive action when applied to the skin and in contrasting its utility especially with mineral fats or petroleum products, he claims well-founded, as he terms them, objections to the employment of the latter as basis for ointments. Let me in this connection quote these objections side by side with my own, which were made after careful investigation some years ago, especially upon vaseline and cosmoline as basis for ointments:

LIEBREICH'S INVESTIGATIONS ON THE ACTION OF MINERAL FATS.*

"Quite apart from the fact that the absorption of medicaments when mixed with pure fat is but imperfectly effected, fat-ointments are subjected to decomposition which may lead to irritation of the skin. It is true that vaseline does not decompose, but it prevents the entrance of medicaments into the skin, so that even poisonous substances when mixed with vaseline and rubbed into the skin produced neither local nor constitutional symptoms of poisoning."

MY OWN INVESTIGATIONS ON THE ACTION OF MINERAL FATS, REPORTED IN 1882,† 1884,‡ AND 1885.§

"Petroleum products, vaseline, cosmoline, etc., possess feebler power to penetrate the skin, if any at all, than animal fats, which have more affinity for the integument. Their absorptive power for penetrating action into the skin is so feeble as to almost cause them to be excluded as such. Irritant ointments of veratria and other substances which I had made respectively of vaseline, cosmoline, and of simple cerate, manifested themselves in the former two preparations as almost inert, while the activity of that made with simple cerate very soon became evident. Further, the petroleum products retain some stimulating constituent left after their manufacture."

It will be seen both from Liebreich's experiments and conclusions as well as my own that the substance employed as a basis for ointments should possess the power of penetrating the integument and in not irritating it. Liebreich has therefore succeeded by his investigations in producing an agent

*British Medical Journal, January 16, 1886.

§The Oleates, an Investigation into their Nature and Action, pp. 58–62.

as a basis for ointments which not only possesses this absorptive action that is so necessary, and that he can justly claim for lanolin, but by its neutrality its own decomposition is out of the question, and consequently it will not irritate the skin. It is a substance, from these valuable merits, which I regard as even superior to lard, the hitherto most acceptable basis for all ointments. Lanolin, Liebreich states, has its origin in keratinous tissue, and is manufactured chiefly from wool, by "transforming the wool fat into a milk, and then subjecting it to a centrifugal action." By this process, he further adds, "a thin milk and cream are obtained, just as when milk is subjected to centrifugal action, and the cream contains lanolin in a pure condition. More than 100 per cent. of water can be kneaded with it, the result being a yellow, very plastic ointment." Through Baker & Co., of Philadelphia, I obtained by importation a quantity of lanolin, with which I have now conducted very many experiments, with good results and the greatest satisfaction. It is an ointment having a yellowish color and a very slight woolly smell, or an odor similar to that of new cloth, which is barely noticeable and is not the least unpleasant. It is neutral in reaction, and has the consistency of ordinary citrine ointment, which it has very much the appearance of, and is soft, smooth, and slightly tenacious. On applying it to the skin, with slight friction it rapidly disappears. It is only decomposed, as it is claimed, with great difficulty, and it readily combines with other fats, oils, and glycerine, forming many most excellent ointments and liniments.

Therapeutic experiments with it, more particularly in my clinic at the Hospital for Skin Diseases, have demonstrated the rapidity with which it is absorbed and well borne by the skin. Cases having eruptions on various parts of the body had lanolin ointment used on one portion, lard ointment on another, and petroleum ointment on still another. The effect of the application of these bases were strikingly different upon the same subject and in the majority of cases. The lanolin was found to be rubbed in with ease, the absorption being rapid and the medicament held in suspension, and in contrast with the drug in the other ointments to be more decided in its impression upon the parts. For example, the employment on the skin of a 5 per cent. carbolic lanolin ointment, and the same quantity in lard and in cosmoline, produced rapidly in the former a numb sensation, less marked in the lard ointment and even less so or almost an absence of effect in that of the cosmoline ointment. The experiments so far conducted show that lanolin requires much less for an application for an effect, and therefore it is particularly economical as a basis for ointments. Again, the slight tenaciousness of the ointment fulfils a most valuable purpose in keeping it in contact with the skin. This property prevents it from greasing up the surrounding parts, or from running off, which it rarely may, even when the integument is most highly inflamed.

The following formulæ are appended as instances of the use of lanolin in my experience of the diseases named:

℞. Zinci oleatis, ℈j.
Lanolini, ʒiv.—M.
For acute eczema, rosacea, and acne.

℞. Potassii iodidi, ʒss.
Lanolini, ʒiv.—M.
For scrofuloderma and scars.

℞. Plumbi oleatis, gr. v.
Lanolini, ʒj.—M.
For erythema, acute eczema, and sycosis.

℞. Naphtholi, gr. x.
Lanolini, ʒij.—M.
For scabies, lousiness, and chronic eczema.

℞. Chrysarobini, gr. xv.
Lanolini, ʒij.—M.
For psoriasis, tinea versicolor, and acne vulgaris.

℞. Olei cadini, ʒj.
Lanolini, ʒiv.—M.
For chronic eczema and psoriasis.

℞. Cupri oleatis, gr. x.
Lanolini, ʒiv.—M.
For ringworm, favus, and tinea versicolor.

℞. Acidi carbolici, gtt. ij.
Lanolini, ʒj.—M.
For epithelioma, lupus, and common ulcers.

℞. Acidi salicylici, ʒss.
Balsam peruviani, ʒss.
Lanolini, ʒss.—M.
For fissured eczema of the hands and feet especially.

℞. Arsenici oleatis, gr. v.–x.
Zinci chloridi, gr. v.
Pulv. marantæ, ʒss.
Ext. belladonnæ, gr. v.
Ext. opii, gr. x.
Lanolini, ʒss.—M.
For epithelioma, lupus, and old ulcers.

℞. Ferri oleatis, ʒss.
Lanolini, ʒss.—M.
For arsenical sores and old ulcers.

℞. Boro-glyceridæ (50 per cent. solution),
Lanolini, āā ʒss.—M.
For scrotal and anal eczema; also eczema of the nose and ears, sycosis and dermatitis.

℞. Ungt. hydrargyri oleatis,
Olei ergotæ,
Lanolini, āā ʒss.—M.
For alopecia.

℞. Acidi boracici, ʒss.
Lanolini, ʒss.—M.
For ringworm, seborrhœa, and bromidrosis.

℞. Hydrastis, gr. iv.
Lanolini, ʒij.—M.
For seborrhœa, subacute eczema, and hyperidrosis.

℞. Lac sulphuris, ʒss.
Thymol, gtt. iij.
Zinci oleatis, ℈j.
Lanolini, ʒss.—M.
For acne rosacea and sycosis.

℞. Plumbi carbonatis, ʒss.
Ext. erythroxyli cocoæ, ʒss.
Lanolini, ʒss.—M.
For acute eczema, erysipelas, and herpes.

℞. Ext. belladonnæ, gr. x.
Ext. arnicæ, ℈j.
Morphiæ sulph., gr. ij.
Lanolini, ʒss.—M.
For furuncular affections, herpes zoster, and impetigo.

℞. Hydrargyri chlor. corros., gr. ij.
Lanolini, ʒij.—M.
For syphilitic affections, lupus, and alopecia.

℞. Ext. conii, gr. x.
Naphtholi, gr. x.
Olei camphoræ, gtt. v.
Lanolini, ʒss.—M.
For paræsthesia and all irritable conditions of the integument.

Philadelphia, Pa.

A CASE OF WIRING THE FRACTURED PATELLA.

BY J. EDWIN MICHAEL, M. D.,

Of Baltimore, Md.

A. W., æt. 43, laborer, entered Bay View Hospital, October 31, 1885, suffering from an ununited fracture of the left patella. His account of himself is not satisfactory. It is about as follows: About a year ago he suffered from an attack of what the doctor called brain fever, during which he was delirious most of the time, and about which he knows nothing, except that upon recovery he found his left leg almost useless on account of a broken knee-cap. How it was broken or how treated, if treated at all, or even when treated, he is unable to say. Upon exposing the knee, a transverse fracture of the patella was obvious. The fragments lay about three inches apart, separated from each other by a deep sulcus. Upon being requested to raise the leg from the bed in the extended position, the separation between the fragments increased to about five and one-half inches, and he was unable to raise the heel from the bed until flexion to very near a right angle had occurred. The patient could walk, but in so doing used the leg as an artificial or paralyzed one, being able to bear his weight upon it only when in the position of full extension. The operation of opening into the joint and wiring together the fragments was proposed and explained to the patient, and gladly accepted.

On November 4, the operation was performed in the following manner: The patient being etherized, the extremity, from ankle to upper third of thigh, was thoroughly scoured with soap and water. The same region was then freely washed with a solution of corrosive sublimate of a strength of 1 to 1,000. The hands of the operator and assistants, all sponges, towels, etc., which were to come near the wound, were freely saturated and washed in the same solution. The instruments were kept when not in use in a solution of carbolic acid about 1 to 40. Carbolized catgut was used for ligature and suture. A transverse incision was made across the extremity about midway between the broken fragments of patella, and the joint freely opened. The web of connective tissue uniting the fragments was found to be very thin. The soft parts being now drawn upwards, the upper fragment was exposed and a thin slice of bone removed with the saw. The lower fragment was next treated in the same way, with the addition that an exostosis of small size was removed from its outer angle with the bone pliers. Holes were now drilled through the fragments, beginning about three-quarters of an inch from the upper margin of the freshened surface, and ending at its lower margin in a slight excavation made for the purpose with the gouge, as recommended by Lister. A silver wire something less than an eighth of inch in thickness was now passed through the drill holes and the fragments drawn together. It was found that considerable traction was necessary in order to accomplish this. The lower margins, however, were caused to meet without the necessity of notching the tendon of the quadriceps. The upper margins could not, however, be brought together, and there was hence a V-shaped notch between the two. I thought this interval would be filled with connective tissue if not with bone, and moreover would be a very good place in which to conceal the ends of the wire, and so disturbed myself no further about it. The wire was now twisted, and the ends bent down into the interval mentioned. The wound was now thoroughly cleansed and dusted with iodoform, a short rubber tube placed at either angle, and the line of incision closed by means of the continuous catgut suture. Another dusting with iodoform, a

pad of iodoform gauze, mackintosh, and a bandage, completed the dressing of the wound. The extremity being retained in the position of full extension, was now encased in a plaster splint and the patient put to bed. On the day after the operation the patient complained of pain at the seat of the wound and received a small dose of morph. sulph. which relieved it. On the third day the temperature reached a fraction over 99°, which was the highest during the progress of the case. From this time the history is monotonous—no fever, no pain, no discharge.

On November 25, three weeks after the operation, the dressing was changed for the first time. The line of incision was found to be solidly healed up except at the points where the drainage tubes kept it open. No movements were attempted, the wound was dressed and the splint re-applied.

December 10, all healed, union between fragments firm, but not osseous. Passive motion attempted and flexion carried to about half its full extent. Shampooing with liniment and frequent passive motion directed. Patient can raise the leg from his bed in the extended position. Is now allowed to walk on crutches, but still wears a splint.

January 15, patient walks without a cane and with no other support than a bandage. Can flex the leg to considerable extent, and has full power of extension. He is now employed as one of the waiters in the institution.

Hospital Reports.

PHILADELPHIA HOSPITAL.

Service of Dr. Theophilus Parvin.

Craniotomy.

I have a case of very great interest to present to you this morning, gentlemen. You will remember that I have had twice before you a woman who was approaching the full term of pregnancy, and who had a severe and irritating cough, and who was losing flesh. You will remember that I told you that when a pregnant woman loses flesh, you can always make up your mind that there is something wrong. It is the rule for a woman to gain about one-thirteenth of her weight during the last three months of pregnancy, and this independently of the weight of the fœtus: she herself should actually gain in weight, and when she does not, you may rest assured that there is something wrong. Now, this case leads me to say something about physical defects in pregnant women, for upon examination we found that there was some consolidation, some tubercular implication of the right apex in this case, and I told you at my last lecture that it was my opinion that women who had or who were predisposed to any tubercular or phthisical trouble ought not to be perpetuators of our race.

Well now, to-day let me say a word about heart disease in connection with pregnancy. In regard to valvular disease of the heart, statistics tell us that two-thirds of all the cases that are noted among pregnant women are of the mitral valve, and I would most emphatically assert that a structurally-diseased heart is a very bad thing for a pregnant woman. Last Sunday this woman's pulse was 120, and she was suffering greatly from shortness of breath; her face was pale, her lips blue, her pulse not only rapid, but feeble as well; during the preceding twenty-four hours she had passed only two ounces of highly albuminous urine, though when she was before you, a week ago, I told you that her urine was free from albumen. In a word, then, she was in a very critical condition. Her feet were very much swollen. To go back for a moment to my remarks about heart disease and pregnancy, I would say that when a cardiopathic woman gets married it is a very great misfortune; and while we cannot always control such matters (for they will see "Helen's beauty in the brow of Egypt"), yet our advice should be strongly against marriage in such cases. As a rule, however, love controls the mind, and the love-sick swain and maiden will rush ahead to a consummation of their hearts' desires despite our most earnest advice. It has been said, and said truly, that marriage is a cure for certain forms of heart disease, but the disease amenable to this kind of therapeutics is not valvular in nature. If such women do get married, we should lay it down as a law that they should not have children; but here, again, it is much easier to formulate the law than it is to secure its enforcement. I would say that the results are to be regarded as more apt to be serious where there is mitral than where there is aortic disease. If such a woman has children, then we should make every effort to have the labors as easy as possible, to avoid all strain on the weakened heart. She should not nurse her children.

Well, now, to go back to our patient. She was in labor from Sunday evening at ten until Monday morning at four o'clock.

Now what ought to be the rule in such cases? The abdomen was more distended than in her former pregnancies. It seemed to me that in view of the woman's critical condition we were called upon to rupture the membranes, hasten delivery, and, if possible to use the forceps, apply them. My resident, Dr. Allen, succeeded, after working for three-quarters of an hour, in dilating the os from the size of a silver dollar up to the usual normal dilatation for labor. The membranes were ruptured, and with the flow of the liquor amnii there was decided relief from the cardiac apnœa. The waters were very abundant, though we could hardly call it a case of hydramnios. It was my hope that the child would be small, as is usually the case when the waters are abundant, and that it would therefore readily and rapidly descend into the pelvis, when we could apply the forceps and complete delivery. Well, to our disappointment, the head did not come down. The position was made out to be the left occipito-anterior of the vertex, and as the os was well dilated, it was proposed to apply the forceps to the head high up, where it was arrested. When you are going to apply the forceps with reference to the sides of the pelvis, I would advise you to use Simpson's or Barnes', while when you apply it with reference to the sides of the fœtal head, you should use a Fay-Hodge, a Smith, or a Davis. Well, in this case we applied Simpson's, but the handles would not lock. When this occurs, you may be sure either that you have to do with a very large head, that your grasp is irregular, or that you have not passed the forceps in far enough so as to be well applied, the edges going over the head, as it were. We made fair traction, and there was some slight descent, but when we remitted traction there was recession of the head. Then we tried Tarnier's forceps, and there was some little descent, but the forceps slipped, and this is a point you must look out for. Be careful that when you draw the forceps out they do not come out empty, for if they do you will feel very much chagrined, more especially if you happen to be pulling with all your might and main, as was once the custom, and have the misfortune to be landed in a heap in the middle of the floor of the lying-in chamber. You will be not only an object of ridicule under the circumstances, but will be also likely to receive a fair share of censure; so be careful that your forceps do not slip. Well, I say they did slip here, so I finally concluded that there was no use to continue this procedure any longer. I now tried to introduce Davis' forceps, and got one blade in. Before you use the forceps, always be absolutely sure of the position. In all cases where there is any doubt, it will be best to introduce the entire hand and feel for an ear; if you feel this organ you know that ears grow on heads, and you are sure of a vertex presentation; and remember that the curved margin of the ear is directed towards the occiput, and this will enable you to make out the position. Well, now I found the cord prolapsed by the side of the head and pulseless, so, therefore, I did not press the introduction of the Davis' forceps, for I felt that it was useless and besides senseless, when the head was remote and the child dead; so I concluded that it would be better to perform craniotomy at once. For this purpose I used Smellie's scissors, and soon delivered the head. You are all familiar with Smellie's scissors, but in perforating the head with scissors, unless you break up the cranium enough to let the brain out, you do not reduce the size of the head. It has been suggested by some that after perforating the cranium we should syringe out the cavity, thus washing out the brain. We should at the beginning make a large perforation and tear away some of the bone by craniotomy forceps, so that we will not be compelled to enlarge the opening subsequently. Tarnier's ovariotomy forceps are good for this purpose. In this case the head was fugitive, and perforation was consequently a matter of considerable difficulty. So that, even where the head is movable, a perforator like Tarnier's is sure to enter and to make a large hole, therefore I would advise you to use it. I used strict antiseptic precautions during and after the operation, and the woman's general condition to-day is good, her temperature being normal; yet here is a woman in whom three unsuccessful attempts were made to deliver with the forceps and where craniotomy was then performed—surely there is plenty of excuse in this case for septic infection, but there was no noticeable traumatism, and the hand was not much in the uterus. I was surprised at the size of the child when it was delivered. I had expected that it would be over-sized, but the measurements of the head were not more than usual. Statistics tell us that the average weight of British children is between six and seven pounds; I hardly think this is heavy enough, at least not for American children. I had calculations made recently from one thousand cases, with the result that in males the average weight is three or four ounces over, and in females three or four ounces under seven pounds. As a rule, the

fourth child that a woman bears is the heaviest. There is another curious fact to be gleaned from this case. It is supposed by some that a process of starving by the mother will reduce the weight of the child, so that in women whose labors have been complicated by very large children a sort of starving process is resorted to. Well now, here was a woman whose tissues were so starved as to cause emaciation, yet the child was full-sized.

Puerperal Sepsis.

Here is a very interesting case, and one that it will be well for you to remember, for this woman was as near death's door as I have ever known mortal to be and recover. I had abandoned all hope, and was looking momentarily for her death; but I have now the pleasure of bringing her before you far advanced on the highway to recovery. The presentation and position in this case were normal, but there was hour-glass contraction, with retention of portions of the placenta. Thirty-six hours after labor I removed these fragments, using Hagar's hard-rubber dilators, which are admirable instruments for this purpose. I believe that in such cases rapid dilatation is less dangerous than the more gradual process. We had no trouble in dilating in this case. The fundus was in the epigastrium, where it ought to have been, for it is not until ten or twelve days after labor that the uterus descends into the pelvis. Therefore, from this physiological fact, you see that there is some foundation, after all, for the popular notion that a woman can leave her bed on the ninth day after labor. The uterus was here above the symphisis pubis, and if it persists in this position, it possesses some value; for if, in connection with fever, we find an arrest of involution, we have a right to suspect puerperal sepsis. When I dilated this os, I scraped, or curetted, the womb, and I would say that, as a rule, it is not necessary to give chloroform for this operation. By means of Emmett's currette forceps and Recamier's curette, we should always clean out the uterus when we have reason to know that there are retained membranes or fragments of placenta. You will run no risk by the operation, but the woman will run a very great risk if you neglect to perform it. When the woman continues ill and at intervals fragments of placenta are discharged, you may feel quite sure that operative measures are indicated. Bring the woman to the edge of the bed, have your dilators and your disinfectant solutions ready. First, disinfect the vagina, your instruments, and your hands, and by passing one dilator and then a larger one, and so on, you will, in a few minutes, procure enough dilatation to enable you to introduce your curette. In this case the fragments of the placenta were so broken down that I could not remove them with the curette forceps; it was like trying to eat soup with a fork. So I was obliged to scrape it away, for which purpose you may use Simon's spoon or Recamier's curette. This process may seem like groping in the dark, but it is not: you will pass your instrument up and scrape towards each tube, and with your disengaged hand on the fundus you will have a very good idea of what you are doing. As soon as I dilated this os, there was a discharge of about half an ounce of horribly-offensive matter, though from the period of confinement there had been daily injections of carbolic acid; and in the masses of decayed matter were noted white spots, little islets, as it were, of placental tissue. When you have scraped down to the muscular coat of the uterus, you will hear a creaking, grating noise, and some authorities advise you to continue until you get this; but I would hadly dare to go this far, preferring to stop a little short of the muscular tissue. After I had finished the scraping, the uterus was washed out with a $\frac{1}{5000}$ solution of corrosive sublimate, which I think is strong enough for these cases. I have a notion that this germicide is frequently used in dangerously strong solutions. I was reading recently of the method in which Chiarri, a famous Italian obstetrician, conducts his cases of labor. The first thing done is to thoroughly spray the external genitalia with carbolic acid, which is continued throughout the labor, so that when the hand enters the uterus it passes through a cloud of carbolic acid, and, as the goddess appeared to Æneas through a cloud, so the babe emerges into the world clouded in an atmosphere of carbolic acid. After birth, the parts are disinfected with a solution of corrosive sublimate of the strength of $\frac{1}{1000}$. Well now, this seems to me to be too strong to be safe, and stronger than there is any necessity for using. To go back to our patient, there has been a steady, though slow, improvement ever since the uterus was cleaned out, and she is now getting well. This has been a very chronic case, for the labor occurred in December. Such a case ought to inspire hope for even the most desperate cases.

Three hundred and thirty-two years before the time of Christ, our ancient father, Hippocrates, recognized this form of disease, but

viewing its etiology differently from us of to-day, he ascribed it to a suppression of the lochia, yet it is noteworthy that he has left us record of the fact that he observed the disease. Of course, we know that in many cases of puerperal sepsis there is no suppression of the lochia, though a characteristic of the disease is that the lochia are very offensive. Later on, Galen taught the same doctrine, but in connection with the suppression of the lochia, he taught that there was an inflammation of the womb. So, for two thousand years, the profession held this Hippocratic doctrine of puerperal sepsis. In the seventeenth century, those whom the late Dr. Meigs was fond of derisively calling *milkmen,* advanced the theory that the disease was mainly due to a derangement of the function of lactation. They held that during all the time there is a supply of milk throughout the circulation, and that during pregnancy it became concentrated in the uterus, while after labor it was transferred to the breasts; but that in some women there was too much milk, and it was secreted by the salivary glands, excreted through the umbilicus, etc.; and in some cases it went back to the uterus and played the mischief. The idea of milk fever has passed away, and some to-day call it *puerperal* fever, which is a vague term, with no definite meaning. We might just as well speak of puerperal coryza, or puerperal scarlet fever, or puerperal measles, or indeed it would be quite as sensible to speak of *puerperal tooth ache,* and write a learned essay on the subject.

Medical Societies.

CLINICAL SOCIETY OF MARYLAND.

Stated meeting held January 22, 1886.

After regular order of business, the following papers were read:

Dr. J. Edwin Michael reported

A Case of Wiring of the Fractured Patella.

(*See page* 421.)

Dr. O. J. Coskery thought it would be of interest to show, in connection with Dr. Michael's case, one that had recovered under the old-fashioned adhesive strap treatment. This case was the result of direct violence—a blow from a crank handle.

Dr. N. G. Keirle exhibited an anatomical specimen illustrating the condition of the joint in an old fractured patella. The union was entirely fibrous.

Dr. Randolph Winslow tendered his congratulations to Dr. Michael upon his brilliant success, obtained in the case just exhibited. In opening the discussion of the subject of wiring the patella for fracture, it is necessary to consider separately the method as applied to 1st, recent fractures, and 2d, chronic cases, in which there is marked impairment of function; for whilst there is great unanimity of opinion in regard to the one, there is great diversity in regard to the other. Where an old fracture remains ununited, and the functions of the limb are seriously interfered with, nearly all surgeons agree upon the propriety of attempting to obtain better results by cutting down upon the knee-joint, and bringing the fragments together with wire, and the case of Dr. Michael is an excellent example of what may be done in such conditions; but in regard to recent fractures, many of the most eminent practical surgeons hold diametrically opposite views. Amongst those advocating primary suture of the patella will be found Sir Joseph Lister and Dr. McEwen, in Great Britain, and Dr. Dennis, of New York, whilst equally as good practical men, as Bryant, Holmes, and Heath, condemn the operation in such cases. Let us consider 1st, whether better results are obtained by wiring than by splints, and 2d, what are the dangers of the operation. In regard to the first proposition I will quote the opinion of Bryant, as found in the last edition of his text book, published in 1885. He says: "Within recent times surgeons have advocated the primary treatment by wiring, and successes have been obtained—some excellent, others indifferent, few better than the average obtained by the treatment above described. * * * I cannot recommend this practice to be universally adopted. It is eminently hazardous; and when we know that in the majority of cases of fracture of the patella treated without operation results are obtained which in exceptional cases alone interfere with life's duties, the treatment by operation stands condemned as a rule of practice." He presents also a most interesting table of cases treated at Guy's in the ordinary way. Of 32 cases, 28 resulted in limbs "useful in every way," and in four there was more or less weakness of the limb; of the four in two the separation of the fragments was but ½ inch, in one 1 inch, and in the other 2 inches. Of those who recovered with useful limbs, a large number pursued laborious occupations, being carriers, sailors, porters, and engineers. One man could climb a ladder with two hundred weight on his shoulder. In one man who had a perfectly useful limb, there was a

separation of the fragments to the extent of 3 inches. In another who could walk well both bones had been fractured, and there was a separation of 2 inches on each side. In another who had good use of the limb, there was 4 inches separation. In the majority there was ½ inch separation, and a satisfactory result.

A specimen presented by Dr. Winslow to this Society two years ago showed a separation of three inches, and yet the limb from which it was taken did not show the least atrophy, and had evidently been perfectly useful. Bony union does not necessarily signify good union, and it is indeed doubtful whether close fibrous union is not preferable. This is exemplified by those cases in which there has been a refracture after varying lengths of time, as the one reported by Stimson, in which a refracture occurred after two months. In a number of the cases treated by wiring immediately, some excellent results have been obtained, but frequently complications or accidents of various kinds have occurred, as profuse suppuration, or necrosis of the upper fragment, or anchylosis or impairment of function, erysipelas, and septicæmia. The ordinary treatment by splints, whilst it may possibly not yield as good results in some cases, probably, when an average is struck, will be found equally as satisfactory, and much less dangerous.

Let us see now what is the mortality inherent to the operation. Mr. John Wood, of London, reports four deaths in the first fifty cases operated on, and one additional from carbolic acid poisoning. Dr. Dennis says there have been no deaths in the second fifty cases, and yet one of his own died of erysipelas. Besides the direct mortality, then, we have the other accidents and complications already mentioned. Dr. Dennis formulates three propositions in regard to the advantages to be derived from operation.

1. The absence of danger to life and limb.

2. Superior results as regards the function of the joint.

3. Greater rapidity of repair.

It has been seen that in the first fifty cases four or five died, which shows there is considerable danger to life, even if more favorable results have been obtained since. From the fact that suppuration, necrosis, and anchylosis have occurred in other cases, it is evident that the second proposition cannot be substantiated, and the discussion narrows down to the third proposition, viz., that there is greater rapidity of repair after wiring, than when treated by splints. This is believed to be true, but are we justified in causing the death of one person in twelve in order to diminish the length of the treatment of the other eleven? or even if only one in one hundred dies, is it justifiable to operate when almost the only advantage is the saving of a few weeks of treatment? Greater rapidity of repair goes for very little when compared with greater safety to the patient. Lister said he would advocate the operation on account of his faith in the antiseptic system; even if all that was claimed, it did not hold good. In conclusion Dr. Winslow said recent simple fractures of the patella do well enough without operation, hence he opposed opening the knee-joint and wiring the fragments in such cases. On the contrary, in old fractures with wide separation of the fragments, and marked impairment of function, he thought the operation ought to be performed. Dr. John Chambers does not think the space between the fragments of the fractured patella ever sufficient to materially interfere with the quadriceps extensor muscle.

He thought that in those cases in which the function of the muscle had been impaired, an effort should always be made to rescue it from its atonic condition by massage or electrical stimulation before any operative procedure was attempted on the joint.

It is his opinion that the fragments always become more or less separated after the limb has been liberated from the splint and the joint is brought into action.

Dr. R. B. Morrison wished to direct the attention of those members of the Society who were interested in these matters and had not already seen it, to a report of 60 cases of the operation for fractured patella recently published in the *Vienna Medical Press.*

Dr. J. Edwin Michael did not wish to be understood as being a disciple of any surgeon who recommends wiring together the fragments of a broken patella *as a rule*, but wishes to have it known that he judges his cases individually, and selects only those that he thinks favorable.

A difference should be made between fractures from direct violence and those from muscular contraction. He only advocates wiring in acute cases which present peculiar conditions; as where the fragments are wide apart, or where the fracture is compound.

He has seen a case in which the limb was perfectly useful, and yet there was an interval of three inches between the fragments of the fractured knee cap. This space was oc-

cupied by firm fibrous tissue. He thinks it immaterial whether the union is fibrous or bony.

Dr. G. M. Sternberg made some remarks upon the

Malarial Germ of Laveran.

It was his intention to present a paper on the subject to the Society, but when he had completed it, it was found to be of such length that it would have taken up the whole evening to read it. He reviewed the work so far done on the subject, referring to the early publications of Crudeli and Klebs on the bacillus malariæ, which organism is now denied an existence. At that time Marchiafava claimed to have seen the same microbe. While in Rome, Dr. Sternberg, through the kindness of Drs. Marchiafava and Celli, had seen the malarial germ in the blood of patients sick of malarial fever. This body is identical with the "small round hyaline body" described in a paper on the pathology of malaria by Drs. Councilman and Abbott and read before this Society last winter.

The organism is possessed of amœboid movements; it is constantly changing in shape. At one stage it appears as a simple round disk; in another arms appear: again motile flagella may be seen, which by their lashing movements set into motion the surrounding blood corpuscles. Of course these bodies are only to be detected by the use of special apparatus. Through the kindness of Dr. Nordman, of Bay View Asylum, he has been enabled to examine the blood of malarial patients during the paroxysm, but cannot state positively that he detected the bodies. He has made similar examinations of malarial blood from other sources, but will not commit himself as to their result.

He considers the evidence very strong in favor of this organism being found in the blood of malarial fever patients. It is not, however, a bacterium. Does not think it possible to disinfect the blood by practicable doses of quinine, but does think the drug may be effectual in restraining the amœboid movements, and that they may finally, by arrest of their development, disappear from the circulation.

Dr. Wm. H. Welsh was much interested by Dr. Sternberg's remarks. He agrees in thinking the evidence strongly in favor of these bodies being found in the blood of malarial fever patients. Called attention to an article by Ehrlich, in which he describes a metaphormosis that takes place in the centre of the red blood-corpuscle, and which takes on stain. This caused considerable doubt as to the correctness of Marchiafava and Celli's discovery; but later publications proved that the body described by them is an organism.

The organism is known as plasmodium malariæ; it is not a bacterium. He thinks it important, as has been suggested by Koch, that in examining blood and other tissues for organisms, that we do not confine ourselves to searching for bacteria alone.

Marchiafava and Celli produced the disease by inoculating persons free from malaria with the blood of patients suffering from this malady.

He does not think one justified in drawing conclusions from the results of experiment alone, but is of the opinion that the natural course of events should always be taken into account.

Since Marchiafava and Celli have not isolated and cultivated this organism, and then produced the disease by inoculation from the cultures, he does not think the etiological role of these bodies *absolutely* established.

Dr. Hiram Woods read a paper on

Foreign Bodies in the Vitreous.

Dr. Samuel Theobold thinks it pretty well established that the electro-magnet is superior to the permanent magnet. The so-called permanent magnet soon loses its power.

He related a case seen by him some years since. The patient had blown into his eye a bit of glass, a fragment of a test-tube that exploded in the course of some experimental work. When seen there was detected a small particle of glass hanging from a shred of iris; in a very few minutes it had dropped into the posterior chamber, and with the exception of a slight temporary inflammation the patient has experienced neither discomfort nor inconvenience since. Vision was absolutely unaffected. The body has now been in the eye about 14 years.

The absence of harm he thinks due to the fact that glass undergoes no chemical changes.

BALTIMORE GYNÆCOLOGICAL AND OBSTETRICAL SOCIETY.

Regular meeting held January 12, 1886. The president, George W. Miltenberger, M. D., in the chair; Wm. E. Mosely, M. D., secretary.

Discussion on Distocia.

Dr. H. P. C. Wilson said that in his own practice, in cases of presentation of the breech demanding interference, he always brings down a foot. If the breech is en-

gaged in the superior strait he pushes it up into the uterus, and brings a foot down, even if it is at the fundus uteri. He never exerts traction in the groin, either with his finger or the blunt hook, and never uses forceps in such cases. With greater experience, turning grows more and more in his favor.

He referred to the confinement of the wife of a friend in Copenhagen, in which case the head presented. After prolonged effort and failure with forceps, the child was removed by embryotomy. He felt certain, from the account he received, that, had turning been resorted to early, there would have been very fair prospects of saving the life of the child.

Dr. B. B. Browne had succeeded twice lately in delivering the child with Tarnier's forceps in difficult breech presentations, where the membrances had been ruptured several hours, the vagina hot and dry, and the breech firmly fixed in the superior strait. In all cases where the membranes are unruptured, or where the breech is not firmly wedged in the pelvis, he would prefer bringing down the feet rather than using forceps.

In reply to a question, Dr. B. said he applied the forceps in these cases to the sides of the pelvis of the mother, and without reference to the portion of the breech upon which the blades would press.

Dr. Neale, in reply to a question, said that in the first case reported, the blades of the forceps clasped the child over its hips. He thought, however, that the forceps would have a better hold if one blade was over the sacrum, and the other was over the anterior aspect of the opposite thigh, which is the method recommended by Dr. Lusk.

Dr. Thos. Opie said that he always made due effort to bring down *both* legs in decomposing the impacted breech or in turning the child. The hand grasping both knees, or one knee or thigh, has always a more secure hold than by a foot, or even both feet, and the traction acts more directly and efficiently on the body.

Dr. Neale wished to say, in regard to Dr. Wilson's remark that he "always went for a foot" in breech cases requiring interference, that he believed there were many cases in which it was practically impossible to bring a foot down, as when the breech already occupied the pelvic cavity and could not be pushed up into the uterus so as to free a foot.

Dr. Thos. Opie read the history of three cases.

Case 1. Pregnancy Complicated with Laryngeal Phthisis, with Subsequent Confinement.

Mrs. M., aged thirty, primipara, had suffered from severe pneumonia three months prior to conception. A brother had died of phthisis at about her age. Laryngeal phthisis set in about the middle of pregnancy. At the expiration of her eighth month, there was great dyspnœa—pulse 120, respiration 30, temperature 102°—and severe pain in the lower lobe of the right lung. This latter symptom was imputed to mechanical causes, from the right lateral obliquity of the uterus. So great was the embarrassment of respiration and pain, that the idea of artificially inducing labor was seriously entertained. On the 19th, labor pains set in at 7 p. m. The dilating stage lasted five hours. At 1 a. m., the head was low in the pelvis, the pulse 160, respirations 60; sweating profuse; countenance indicative of great fatigue. The child's movements and pulse showed it to be well and strong. The forceps were applied and the child delivered in excellent condition. There was no laceration of the perineum, and the uterus contracted well. There was no relief to the function of respiration. The pulse continued its same rapid stroke, the dyspnœa was quite as great as ever, and death closed the scene as if from the accumulation of carbonic acid in the blood. The child was well developed and vigorous, having drained the mother for its own support. I presume there are few supporters at present of the theory that pregnancy retards phthisis by derivation and revulsion. This case seemed one in which the disease was aggravated, if not developed under the trials of gestation.

Case 2. A Unique Presentation.

Mrs. R. H. was delivered by me in 1884 of a still-born child at full term. The os was dilated by Taylor's narrow-blade forceps and the traction rod forceps applied above the superior strait. The head not advancing under reasonable force, and the child being dead, cranioclasty was performed. Following her confinement she had severe metritis. In twelve months from her first labor, I was called to her in premature delivery of a dead child at eight months. The presentation was in my experience unique. Both hands and one foot were presenting in the os, above the superior strait, and the funis was prolapsed into the vagina. Inspection and palpation showed the shape of the abdomen as well as the contour of the uterus to be normal. The child was doubled upon its abdominal plane, its dorsal region corresponded with the fundus uteri, the head was on the shelf of the right iliac fossa, the ulnar surfaces of the hands, and the os calcis

of the presenting foot, looked towards the left iliac region. Chloroform was given to complete anæsthesia. The missing foot was found, and this and its fellow seized with my right hand only partially introduced into the cavity of the uterus. The left hand assisted in the act of version through the abdominal wall, as in the combined or bifolar method introduced by Braxton Hicks. The membranes had been ruptured for three days, but no serious difficulty was realized in turning the child. In view of the softened and yielding state of the child's tissues, it became most important that traction should have been made with both legs. The atony of the uterine walls fully compensated in turning for the disadvantage from the loss of expulsive power. When the head was extracted the occiput was pushed up, the chin was flexed, and simultaneously pressure was made by an assistant. The position as at first diagnosed could only have occurred in a dead child. I think it was originally a right occipito-iliac position. The child having lost its resiliency first assumed, under the uterine contractions, an oblique position ; and nature, unequal to the task of delivery by the head, began the work of self-turning by the feet. The patient made rapid convalescence, uninterrupted by a single abnormal symptom.

Case 3. Diagnosis of Twins. Double Battledoor Placenta.

Mrs. B., primipara, delivered January 5 of twin girls at the end of the eighth month of pregnancy. Was called a month before labor to examine what proved to be a hernia in left inguinal region. An opportunity was given for a thorough exploration of the abdominal tumor. Inspection and measurement showed the transverse diameter of the uterine globe to be as long as the vertical. Auscultation revealed on the extreme right a heart sound, and a loud placental murmur at a corresponding site on the left side. A number of small fœtal parts not clearly distinguishable were found, too many and some of them too far removed from the fœtus on the right side to be imputed to that child. Twins were predicted. The placental souffle likely masked the heart-sounds of the child on the left side. The first child was born after a tedious labor of twelve hours, the waters breaking in advance. The second child was born one hour later. The membranes broke when the head was dilating the vulva. The placentas were firmly united and the cords were inserted very near the ridge where they seemed welded together. They were so close together, and so near the line of union, as to give the appearance of a double battle-door placenta, Each fœtus had its own amnion and chorion, but there was a common decidua. The close union of the placentas on the left side of the uterus, coupled with the fact that both children were of the same sex, makes it highly probable that the two ova were deposited in the same fold of the decidua vera, that they came from the left ovary, and were from the same Græfian vesicle.

CHICAGO MEDICAL SOCIETY.

Meeting, February 15, 1886.

Discussion on Digital Exploration of the Bladder in the Male. (*See page* 391.)

Dr. E. Andrews suggested to the members that this subject was more important than has formerly been supposed. The former examinations made in these cases were very imperfect, and though the finger used occasionally to be put in the bladder, it was not dreamed that the whole circumference of it could be reached. He thought it should be impressed upon the members of the profession that the bladder can and ought to be explored.

The President thought this procedure for diseases of the bladder so new that it might be called novel, and it seemed singular that at so late a day the bladder should be explored in this way, when surgeons have so long known that the bladder could be opened in many ways without injury to the patient. He thought the profession greatly indebted to Dr. Belfield for his remarks.

Dr. W. M. Axford thought an incision in the perineum might facilitate a cure in cases of fistula, which at present are very difficult to cure, but did not know that it had ever been tried. We do know that renal fistulæ are very difficult to cure, probably because the urine is continually running over them. The procedure is practically harmless, and may effect a cure.

Dr. W. T. Belfield said in conclusion that this procedure of inserting a drainage-tube through the perineal wound for curing fistula of the urethra is mentioned in Harris's book, and seems to work with entire success. There was one point upon which he congratulated himself, viz., the discovery of cyst of the bladder. So far as he knew, nothing of the kind had been recorded in either the pathological or clinical literature of the bladder. The misery that it can cause is illustrated in the case under discussion, and from its nature it offers every hope of a cure.

Notes on Genito-Urinary Surgery.

Dr. Axford said that he believed gleet is due to a stricture of the urethra, and can be cured by curing the stricture. He believed that dilatation cured a stricture by exciting inflammation at the seat of the stricture, and thus causing the absorption of the exudate. In the treatment of strictures, he believed that perineal section is best in strictures which are deep-seated, narrow, or unyielding, or complicated by fistula or urinary infiltration; internal urethrotomy in all strictures of the meatus or fossa navicularis, for they will not stretch. For other strictures he would advise, as the case demanded, dilitation, divulsion, or internal urethrotomy. If the stricture is resilient, divulsion, or internal urethrotomy, preferably the latter. He believed the dull pain in the back, and at times in the head, during the later stages of gonorrhœa, to be due to urethral reflexes. Cure the gonorrhœa or stricture, and these disappear.

He cited cases in which severe cephalalgia and skin diseases had been cured by curing strictures by internal urethrotomy. Also, cases in which dysuria and vesical discomfort had been allayed by slitting the meatus. In female urinary troubles, after excluding uterine disease, he had given relief by digital dilatation of the urethra.

Dr. E. Andrews referred to the point whether there is any danger or not in urethrotomy. European statistics show a considerable amount of danger in operations for stricture. He did not know the reason for mortality in Europe, for he thought it the general experience in Chicago that men do not die of these operations. Long ago he had left off keeping count of the cases he had operated on, and could not recall an instance in his own practice or that of any one else in this city in which the patient died in consequence of the operation for stricture. As to the question of divulsion or cutting, he had performed the two operations indiscriminately, sometimes both on the same patient. He thought divulsion and cutting produce precisely the same result. Some strictures will stretch out under the divulsor and go back again, and cutting is better for these cases, but neither appears to be dangerous. He has found divulsors from New York instrument-makers repeatedly breaking down under strong strictures. Otis's instrument he thought exceedingly strong, but even that had failed in one instance. He expressed the belief that divulsion, thoroughly carried out, is as safe as cutting.

Dr. F. E. Waxham referred to a unique case coming under his care, of stricture in a child aged four years. He was convinced, however, that stricture is very rare among children. This was the only case that had come under his observation. Otis alludes to two causes—masturbation and gonorrhœa. In this case he found no history of gonorrhœa, and the mother denied the practice of masturbation. The child was put under the influence of ether; the stricture was so closed that he could only enter the bladder by means of a very fine bougie; this was followed by a larger one, this by a small catheter, and this by a steel sound, and the child was then able to pass the urine without difficulty. Before dilatation the child would undergo the greatest suffering every time he passed water, would scream and strain for several minutes, and oftentimes strain so severely as to cause evacuation of the bowels. After the first dilatation the child did nicely for a week, and then was as bad as ever; the second dilatation was three weeks ago, and there has been no further trouble.

Dr. A. B. Strong asked if the cure was permanent after cutting unless constantly followed up with the catheter. He wished to know if there is anything better than simple dilatation. Cutting and divulsion are more rapid, but he thought gradual dilatation offered as good and permanent results.

Dr. W. T. Belfield suggested two points in Dr. Axford's paper that required notice, the value and the safety of cutting. He thought it absolutely imperative that we limit our cutting operations strictly to the pendulous urethra. This was not merely a theoretical and anatomical consideration, but a practical one. He thought Dr. Axford, in speaking of the three methods, stretching, divulsion, and cutting, omitted one of the most important, viz., the use of a constant electric current. Although this had not received a great deal of attention from the profession, he thought anybody who tried it would never give it up. It is said to produce the most permanent results, and is convenient and easy. He had tried it in his own practice, once in the hospital where he had the privilege of cutting, but tried the battery out of curiosity and found it worked nicely, and again in private practice where it was extremely important to the patient that no perineal section should be done. As to stretching the female urethra with the fingers, he thought it dangerous. When house surgeon in the county hospital he had seen a woman die of peritonitis when that was done. He thought the best instrument for this purpose to be Stein's dilator, which has a continuous dilatation.

Dr. W. L. Axford said, in conclusion, that dilatation always has to be followed out by the occasional passage of the sound for an indefinite period of time; all the patient's life. If the stricture is divided clear through, Dr. Otis claims that a perfect cure will be made and no after-treatment will be necessary. Dr. Axford thought that Dr. Otis, although an extremist on this subject, is about right. As to cutting in the membranous urethra, he did not think any one would do that. He had never had experience with the galvanic current, had heard it recommended and also discountenanced. In dilatation of the female urethra he had always used his fingers and succeeded first-rate. Would always prefer to use his own hand, as no instrument equals the human hand.

Dr. H. T. Byford read a paper on the

Production and Prevention of Laceration of the Perineum,

with description of an unrecognized form. Illustrated. For the purpose of illustration the perineum was divided into two parts, the vulval or external, and the vaginal or internal. The former lies external to the muscles and the latter includes all the rest. When the perineum is slightly stretched by the head two rings may be felt by hooking the finger over the fourchette; an external ring marking the edge of the vulva and an internal ring marking the edge of the muscles and fascia about the vaginal orifice. Upon the positions and relations of these rings depends the safety of the perineum. When the occiput engages in them before the forehead passes the coccyx, the fourchette and muscular edge are pressed downwards, and the perineum but little bulged, and not at all endangered. When the occiput does not engage in the rings before the forehead leaves the coccyx, the fourchette is pushed upward before it, the perineum stretched from three to four inches antero-posteriorly, while part of the propelling force and nearly all of the directing force are lost before the head passes the rings and is born. The head in such cases has a greater distance to travel before delivery, involving los of time and strength.

The author described an obscure but not infrequent form of rupture, in which separate muscular fibres and portions of the fascia give way all through the perineum, or through a region of it, without involving skin or mucous membrane. Frequently there were not enough unruptured fibres left of the tissues to insure contraction and involution, and thus prevent displacements of the uterus. A persistent flabbiness is the chief diagnostic sign. To prevent rupture Dr. Byford advised: 1. To gain time for dilatation without injury to the deeper tissues, by favoring a slow advance of the head over the floor of the pelvis. 2. In order to secure sufficient dilatation of the vulval and vaginal rings to make the occiput ride over them instead of hooking under them by keeping the membranous pouch intact, or in its absence early resort to artificial dilatation, rather than wait for the fourchette to be thus hooked up over a bulging perineum, and then resort to the ordinary methods.

Dr. G. H. Randall thought that by directing the head many perineums might be prevented from rupturing. We sometimes fail to direct the head and manipulate the perineum as each case requires, because the woman is not in the proper position. Formerly he had delivered most of his cases in the dorsal position, but not being satisfied with the way he was able to manipulate the perineum and head, he had tried the lateral position, and it seemed a great improvement. He could now support the perineum by directing the head with a great deal more ease and effect than before, and it seemed to him that the lateral position is preferable to the dorsal.

Owing to the lateness of the hour, Dr. R. G. Bogue deferred reading his paper on "A Case of Oöphorectomy and of Nephrectomy," but exhibited specimens, and said: "The specimen that I have here is that of a remarkable cystic ovary in which both ovaries, with a large portion of the fallopian tubes, were removed. I have but one to present, though the whole surface of the ovary, or ovaries, was studded with small cystic tumors. The case was one of long-standing invalidism, and attended with a great deal of suffering. Finally, the question of removal of the ovaries came up, and it was decided to remove them. They were removed, and the patient recovered. The other specimen that I have is a wax model of a calculus which was found in the pelvis of a kidney during an operation for removal of fibro-nephroid kidney. On opening the loin, making the posterior operation, and cutting to the kidney, it was found to be immensely distended and filled with pus, and in the pelvis of the kidney was quite a large calculus. The calculus was claimed by the family and given them, a wax cast of it being retained. The patient from whom this was removed did not recover."

Editorial Department.

Periscope.

Trephining in Traumatic Epilepsy.

In the *Journal of Mental and Nervous Disease*, Dr. Charles K. Mills relates a case operated upon by himself and Dr. J. W. White, of a farmer, æt. 26, suffering from epilepsy consequent on a gunshot wound.

From the scar of the wound and the patient's account, it is evident that the ball entered the scalp just above the right temple. He has been told that the surgeon introduced a probe "three and a half inches and brought out some of the brain-substance on the end of it."

Examining his head, which had been shaved, *two* scars were found close together in the scalp, and an irregular fracture was felt spreading over a space of about one square inch, at a position about two inches to the right of the median line, and one-half to one inch, in front of the coronal suture. There seemed to be a small depression, surrounded by a slight elevation of the skull, in this locality. The position of these scars and of the fracture beneath the frontal bone corresponded to a point about the junction of the middle portion of the first frontal with the second frontal convolution. The middle of the fracture was at a point about two inches in front of an imaginary line corresponding to the fissure of Rolando; the whole area of fracture was certainly well in advance of the ascending frontal convolution and the entire so-called cortical motor zone.

In the convulsion witnessed just prior to the clinic hour he was completely unconscious; his face and all his limbs, as well as his head and trunk, took part in the spasm; the eyes were distorted; his whole body was twisted somewhat to the right; the spasms were tetanic in character; the limbs were in conditions of tonic spasm in extension. When moved, they were moved as a whole, the rigidity remaining. The spasms were not localized; they were not confined to one limb or to one side of the body.

For several reasons these spasmodic seizures were probably due to irritation of the dura mater, what might be termed dural or meningeal spasms. They were not due to irritation of the cortical motor zone, the form of spasm sometimes spoken of as a Jacksonian epilepsy. The scalp wound and fracture, in the first place, were in a position well in front of this motor or Rolandic region. Lesions of the motor cortex cause disorders on the opposite side of the body; irritative lesions cause monospasm or unilateral spasm of the opposite side. These spasms usually show themselves in a definite manner, both as to localization and mode of action.

The operation was performed by Dr. White.

The patient having been thoroughly etherized, a horse-shoe flap of large size was made by Dr. White. No adhesions or extravasations were found beneath the scalp. The skull was found to be fractured in the position already described; the entire area fractured could be covered by the trephine used by Dr. White, which was one of the largest size. The anterior portion of the trephine very quickly made its way through the skull, and subsequently it was found that at that point the inner table was partially separated from the outer. The button, irregular in shape and thickness on account of the old splintering of the inner table, was removed with great care and without wounding the dura mater, and it was then found that the portion remaining was adherent to that membrane. By careful dissection this fragment of fractured bone was finally removed. Two very small spicules were picked out of the wound with forceps, and an irregular jagged mass of bone about half an inch in its greatest length was found imbedded in the dura mater, one of its points passing through it into the brain substance.

The operation was performed with the most rigid antiseptic precautions.

Safe, Simple, and Effective Mode of Treating Prolapse of the Rectum and Hemorrhoidal Tumors.

Dr. Q. C. Smith thus writes in *Gaillard's Medical Journal:*

By the method here proposed I have treated three cases of prolapse of the rectum and about a dozen cases of hemorrhoidal tumors.

The cases of prolapse of the rectum were all the result of parturition, and two of them were, or appeared to be, complete, *i. e.*, all the coats of the bowel had passed out through the external sphincter.

These cases of rectal prolapse and hemorrhoidal tumors were treated by injecting into

the tissues with the hypodermic syringe an eight-grain solution of muriate of cocaine, plus an equal volume of phenol sodique.

The quantity of this solution injected varied from twenty minims, in small hemorrhoidal tumors, to one ounce in prolapsed rectum.

One injection was sufficient to cure hemorrhoidal tumors in all my cases, while two to four trials were found necessary to cure prolapsed rectum. The syringe point was introduced at the most prominent point of the tumors—large or small—and thrust boldly to the most vascular part of their base, and a liberal portion of the solution deposited, according to the size of the tumor. Then the balance of the tumor was well saturated with the solution. After injecting hemorrhoids no topical treatment was applied, except a daily wash of dilute solution of boric acid, as hot as could be borne. After injecting prolapsed rectum a mild antiseptic healing salve was kept applied. The following formula was found very efficient:

℞. Iodoform, in *fine* powder,
Balsam Peru,
Oil of camphor,
Oil of sassafras, āā ʒss.
Pine tar,
Castor oil,
Powdered aloes, āā ʒj.
Subnitrate of bismuth enough to make a stiff salve.

S.—Apply thoroughly twice a day, and cover with a soft cloth.

Before applying the salve each time, the parts were well washed with the syringe, soap suds from Packer's tar soap, as hot as could be borne, being employed for the purpose.

In addition to whatever general internal treatment may be indicated in any given case, I am in the habit of directing, with excellent results, something like the following:

℞. Fl. ext. witch-hazel, ʒss.
Sat. tinct. horse-chestnut, ʒj.
Muriate of ammonia, ʒj.
Glycerine, ad ℥iv.
M. ft. sol.
S.—A teaspoonful three times a day, just after meals, on alternate days.

℞. Muriate of hydrastin, gr. xxiv.
Ergotin, gr. xij.
Ext. capsicum,
Ext. ipecac.,
Aloin, āā gr. vj.
M. Make 24 pills and silver-coat.
S.—One pill three times a day, just after meals, on alternate days.

These last two prescriptions should be administered regularly, on alternate days, as long as the hemorrhoids or prolapse give trouble, and for several weeks after they have ceased to do so.

For bringing hemorrhoidal tumors to view, O'Neal's rectal speculum was found most convenient, though in some cases Woodward's and Sims' rectal speculums served a good purpose. After operation on hemorrhoids patients were allowed to attend to their ordinary business at pleasure, and a majority of them did so.

The cases of prolapsed rectum were confined to bed until cured, which was in the mildest cases about two weeks, and in the two severe or complete cases about four weeks. They were then allowed to move gently about the room, but the patients being parturients, the horizontal posture and quietude were doubly indicated. No general anæsthetic was found necessary in any of these cases, as the operations produced but little pain or subsequent soreness. No inflammatory reaction followed the injections.

I have used various medicaments for injecting hemorrhoids, all with more or less success, never having met with any deplorable results; but the eight-grain muriate cocaine solution, in connection with an equal volume of French-made phenol sodique, has proved the best that I have tried.

In conclusion, the writer begs to state that he is familiar with what has been published in reference to this subject in standard and periodical literature for the last twenty years, and hence claims no originality in the treatment outlined in this communication.

A Case Illustrating an Unusual Cause of Obscurity in the Detection of a Foreign Body.

Dr. Wm. Barton Hopkins thus writes in the *Southern Clinic:*

Wm. L., aged 25, was admitted to the Episcopal Hospital for shot-wounds and other injuries inflicted upon him during an assault, November 29, 1884. He was found to have sustained numerous incised punctured wounds at various points over his back, and a fracture of a metacarpal bone in his left hand. He was also badly bruised, and showed by his general condition that he had had a very rough handling. None of the wounds appeared to have penetrated the chest; indeed, all seemed to be simple, and were so treated.

Two weeks after his admission, attention was attracted to a reddened prominence over the head of the left humerus. It was hard and unyielding to the touch, though evidently about to suppurate. It resembled somewhat the preternatural prominence of

the acromion after luxation of the humerus, although no luxation or fracture existed. An exploratory incision revealed the presence of a foreign body, which proved to be the blade of the knife, deeply and firmly buried in the head of the humerus. A firm hold of it was taken with sequestrum forceps, and it was withdrawn. It was two and a quarter inches long, and had been driven two-thirds of its length into the bone. The staining produced by the bone upon its polished surface showed with real accuracy the depth and position it had occupied in the bone, and portrayed in a very remarkable manner the cancelli, which resembled the markings on a gun-barrel, and the outline of a portion of the anatomical neck of the humerus.

It was found on questioning the patient more particularly in regard to his posture during the assault, that he had attempted to protect himself, while he was being stabbed, by clasping his hands behind his neck. It therefore became evident that a wound situated over the left scapula, quite three and a half inches posterior to the point occupied by the knife-blade when found, had been the wound of entrance; and that the knife having entered the head of the humerus, while the latter was in a state of extreme rotation, the broken blade, when the arm assumed its natural position by the side of the body, had been carried far forward beneath the skin. Had the patient been directed to clasp his hands behind his neck, the knife would doubtless have presented itself at the wound over the scapula, through which it could have been extracted without necessitating the second incision.

The foreign body in this case narrowly escaped remaining undiscovered; indeed, if it had broken off with only a little less projection from the bone, its presence would never have been discovered, unless it had occasioned subsequent bone or joint disease. The case is therefore of interest as furnishing an almost unique example of movement of a joint causing difficulty in the detection of a foreign body.

The Influence of Operations on Tuberculosis.

At a recent meeting of the Paris Surgical Society, an interesting discussion took place on the effect of surgical operations on the course of tuberculosis. M. Mahon, an army surgeon, forwarded notes of two cases. A soldier aged 24, son of a phthisical father, entered the hospital with a tubercular affection of the fourth and fifth metatarsal bones. Resection of the bones was performed. Fever soon set in, and the synovial membranes of the foot were affected. The leg was amputated. The patient rapidly recovered, and his health continued excellent. The other patient was also a soldier aged 24. He entered the hospital for arthritis of the knee subsequent to a fall. Three punctures were made. The first fluid that escaped was serous; afterwards it was purulent. Arthrotomy was performed, and symptoms of pulmonary tuberculosis were manifested. There was hectic fever, and severe pain in the articulation. The limb was amputated; and, although there was improvement, the patient died. M. Mahon considers that surgical operations do not exercise any influence on visceral lesions, and that the cases above described indicate that the external lesion is the principal factor in the morbid process, and that surgical treatment often results in cure, always ameliorates the condition, and often arrests the visceral lesion. M. Chuvel believed that in similar cases the necessary operations should be performed as early as possible. M. Desprès believed that patients with tuberculous lesions ought not to be operated on. M. Lucas-Championnière counseled operating, and cited M. Ollier's opinion. According to M. Ollier, partial operations are not more favorable to generalization of disease than radical measures. M. Lucas-Championnière believed that resections and all operations that cause suppuration are more dangerous in tuberculous patients than amputations. M. Verneuil counselled operating to remove pain, but always radically, not partially. M. Berger stated that formerly he believed that operations provoked generalization, but subsequently he has seen operations exercise a favorable influence on pulmonary lesions. MM. Pozzi, Richelet, Polaillon, and Le Fort, also counselled surgical operation in the presence of tubercular lesions when called for.

Terpene in Pulmonary Lesions.

Dr. Descroizelles, Physician to the Hospital for Children, in Paris, has successfully treated with terpene a case he describes as pulmonary tuberculosis or chronic bronchitis simulating tuberculosis. The patient was a boy, 8½ years old, small and delicate; he had been previously treated at the same hospital for pleurisy on the right side. He coughed, vomited, and spit blood, had night-sweats, completely lost his appetite, and was too weak to move. Very little could be learned concerning his antecedents. In the right infraclavicular region, there were dull-

ness on percussion, a cavernous *souffle*, and subcrepitant *râles*. The sputa were abundant, both mucous and purulent, and mixed with blood. The axillary temperature rose to 38.6° Cent. (101.5° Fahr.). The pulse was 120, and respirations 40. The chest over the part affected was painted with tincture of iodine, and a gramme of phosphate of soda was given daily. The child grew worse, hæmoptysis occurred several times, and there was alternate diarrhœa and constipation. The dullness on percussion became more and more marked at the apex of both lungs, but especially on the right side, where moist *râles*, almost gurgling sounds, were heard, also a cavernous sound. On the left side moist crackling sounds had replaced dry crackling sounds. The child grew weaker, and refused food; his cheeks were sunken and flushed, and death seemed imminent. Glycerine and creasote were substituted for phosphate of soda, without any good result. Dr. Descroizelles then decided to administer terpene. Two grammes of this substance were dissolved in 40 grammes of alcohol and 20 of distilled water, and the child took three or four teaspoonfuls of this mixture daily. A marked improvement followed; less sputa was expelled, and they were free from blood; the appetite increased, the general condition improved, and the patient became convalescent. Lime-phosphate and gentian wine were given instead of terpene. In the interval between the beginning of September and the middle of November, the pulmonary symptoms disappeared, and the auscultatory sounds were normal. The child was sent into the country, apparently re-established in health.

Symmetrical Synovitis of the Knee in Hereditary Syphilis.

Dr. W. H. Clutton thus concludes an article in the *Lancet*, February 27, 1886:

To recapitulate in a few words the principal features of the condition which was demonstrated by these few cases, one would say that the synovitis was symmetrical, affecting only the knees; that it was of a chronic and painless character, and that all the patients were the subjects of hereditary syphilis. I can offer no satisfactory explanation of the facts here recorded, but must content myself with drawing attention to a few clinical symptoms. At the same time I would like to point out that if the condition which is now under consideration be really due to hereditary syphilis, the similarity between interstitial keratitis and this symmetrical synovitis is so marked as scarcely to require any lengthened explanation. Both knees, like the eyes, are, in my experience, sooner or later affected, and often with an interval between the commencement of the symptoms in each joint. Both diseases are exceedingly chronic, and produce little or no destructive changes in the tissues involved, neither suppuration nor adhesions having occurred in any of the cases that came under my observation. They are also both liable to relapses, and not very amenable to treatment. The age of the patients is another and striking point of similarity, for seven out of the eleven were between eight and twelve years of age. In two cases the symptoms arose at much later date, but this also occurs in interstitial keratitis, so that even in its rarer forms it corresponds with that disease in this particular—that of the age of the patient. I am at a loss to explain why the knees should be affected in preference to other joints. It is probable that, with further observation, the knees will not be found to occupy this solitary distinction, and that other joints will be seen to be affected in a similar manner. But up to the present time I have not seen this chronic symmetrical synovitis, which appears to be associated with hereditary syphilis, in any other joints beside the knees. That it should be symmetrical is only what one expects from our knowledge of the similar manifestations of the disease at this period of life.

Electrolysis in the Treatment of Port Wine Mark.

As a sample of the success which Dr. W. A. Hardaway claims from this method of treatment, we append the following case which he reports in the *St. Louis Courier of Medicine* for March:

This was a dark-skinned young man, who had a triangular mark extending, as regards its base, from one angle of the eye to the other, and running to an apex at the junction of the nose and lip. When he first came to me five years ago, I made a little operation on a small outlying portion about the size of a dime. I then advised him to wait several months to see how matters would turn out. He did not return to me for eight months for further work, but he was induced to come back by the fact that the operation had been successful. From this time on he would come into the city about every six months and stay two months at a time. The result has been very gratifying. The patch is but little visible, whereas formerly the young man had a most forbidding aspect. I have noticed that even on the most completely

worked-over places now and then a little pin-head-sized red spot will appear, which I again destroy. There has been nothing like an attempt at a general return, however. A letter which I have received from this patient will give a good idea of his estimate of the results, and in such cases, the patient is as well qualified to judge as any one else. Under date of July 25, 1885, he writes as follows: "Everybody agrees that the work so far has been a success. The lower part and on the nose is almost clear, but immediately under the eye, where it used to swell so, it is a little red yet, but not a dark red as at first. I am well satisfied that if the mark had been a little distance from the eye, it would have been gone by this time."

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. C. W. Dulles, of Philadelphia, has reprinted his strictures on Pasteur's method of treating hydrophobia. He considers that it is wholly illusive.

——In a reprint before us, Dr. W. R. Whitehead, of Denver, Col., describes a new apparatus for making extension and counter-extension at the ankle-joint.

——An instructive article on "Southern Florida as a Winter Sanitarium," appears as a reprint from the pen of Dr. Wm. A. Edwards, of this city.

——A series of biographical sketches of early physicians in Philadelphia, in the form of an address by Dr. J. J. Levick, has considerable local interest.

——The most complete summary of our knowledge about the therapeutic properties of cocaine is a work of over a hundred pages entitled "Coca Erythroxylon and Its Derivatives," published by Parke, Davis & Co., Detroit, for gratuitous distribution to the medical profession. We advise our readers to apply for a copy of it.

——The Society "for the Restriction of Vivisection" maintains a lively activity in pamphleteering. Three of its recent publications are before us—its third annual report, an answer to Dr. Keen, and another answer to the published statements of Drs. Mitchell and Wood. Those who would obtain these can do so by addressing the Society at its office, 1002 Walnut street, Philadelphia.

BOOK NOTICES.

Materia Medica and Therapeutics. By John B. Biddle, M. D. Tenth edition. Edited by Clement Biddle, M. D., and Henry Morris, M. D. Illustrated. 8vo., pp. 524. Price, cloth, $4.00. Philadelphia: P. Blakiston, Son & Co., 1886.

This popular treatise has received at the hands of the editors a thorough and careful revision, which included not only the rewriting of a number of articles, but the introduction of an equally large number, treating of the therapeutic novelties which have been brought to the notice of the profession since the preparation of the previous edition. This labor has been judiciously performed so as to give all the necessary information without unduly augmenting the bulk of the volume. We have no doubt the treatise will continue to enjoy the favor of the profession, both students and practitioners.

The Year-Book of Treatment for 1885. 8vo. Pp. 316. Philadelphia: Lea Brothers & Co.

The plan of presenting all the therapeutic advances of a past year in the compendious form of a year-book has been repeatedly tried in this country, but we believe no such endeavor has survived its second or third year. They have been meritorious enough, but not popular. The present compilation, by a number of different hands, is good of its kind, though not superior to some of its predecessors. It supplies the reader with a sufficiently full account of all the conquests, real or supposed, within the domain of therapeutics during the year 1885. The collations have been judiciously made, and from a wide range of authorities. As in these respects it deserves success, we wish for it a longer life than its predecessors in the same field.

The Adirondacks as a Health Resort. By Joseph W. Stickler, M. D. 12mo., pp. 198. New York: G. P. Putnam's Sons. 1886.

This is a timely volume, and from personal observation in numerous cases we can heartily endorse the author's high opinion of the climate of the Adirondack region in phthisis, acute and chronic bronchitis, asthma, hay fever, neurasthenia, and other affections. Indeed, we go so far as to believe that weighing all advantages and disadvantages, this is the most eligible locality within the area of the United States, both as a summer and a winter resort, in the class of diseases named.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

A METHOD OF DIAGNOSIS IN CHRONIC KIDNEY DISEASE.

It is well known that there are many cases of serious organic disease of the kidney wherein it is incapacitated from properly doing its work, yet where we fail to find either albumen or casts. In such cases we will have many of the obvious symptoms of chronic renal degeneration, but failing to find either of these important conditions, it is difficult to reach a diagnosis. In such cases, Dr. Morris Longstreth, of this city, suggests a means that will prove valuable. He selects some particular ingredient of the urine, say, for example, the chlorides: To a certain bulk of urine he adds, drop by drop, a solution of nitrate of silver of a known strength. This precipitates the chlorides as a white cloud. When the addition of a drop of this solution fails to produce any cloudiness we know that the chlorides are all precipitated. The amount of the chlorides is then estimated and the relation of this amount to the whole bulk of urine passed in twenty-four hours, as compared with the relation it ought to hold in health, will tell us whether the kidneys are secreting or excreting as much of the chlorides as they should normally. If the chlorides are deficient, then the assumption is that all the other solid elements of the urine are deficient and the renal function is faulty. This is a much simpler method of analysis than that for urea, and promises to be very satisfactory in these doubtful cases.

EMBOLI IN PREGNANCY.

Professor Parvin calls our attention to the very important fact that during pregnancy, when a woman has varicose veins, her danger is not only from the rupture thereof, but a thrombus may form in one of these dilated veins, it may become detached, and being carried to the lungs form a pulmonary embolism, with rapidly fatal results. Such a danger is a very real one, and its importance should not be underestimated. We are induced to utter this word of warning because we believe that it is usual among physicians to make very light of a varicose condition of the veins during pregnancy. But when we realize the dual danger of rupture and embolism, we should thoroughly appreciate the importance of prophylactic measures, which, according to Dr. Parvin, should consist in placing a pledget of soft linen over the varicosities, over which a flannel bandage, from the toes to above the varicose veins, is to be worn during the day and removed at bedtime.

THE PREVENTION OF POISONOUS INFECTION.

Physicians are not rarely affected by poisonous ulcerations, or by the virus coming from the dead body. Whenever an infection of this kind occurs, there first appears a small vesicle containing a serous fluid. Dr. Ullmann (*Ver. Bl. d. Pf. Ærzte*, 1, '86) had occasion to observe recently several such cases, and he found, on testing these vesicles with a ten per cent. watery solution of carbolic acid, which is applied every three or four hours, that the vesicle dries up, and no further infection occurs.

A careful observation will show that most smaller and larger boils, if not all, as also furuncles, commence with the formation of a minute vesicle, about the size of a pin's head, and in the centre of which usually a hair grows. These vesicles, if left to themselves, end in the formation of pustules, small abscesses, or furuncles. It might, therefore, be well to try in all these cases Ullmann's treatment as an abortive method. The poison in such cases has probably been carried there either by an insect or by the prick of a needle or pin which had been in contact with some obnoxious substance. In others again the disease germs may have been derived from the blood, and the micro-organisms may find an exit from the body through the channels mentioned. This especially occurs, perhaps, when a number of pustules or of small abscesses break out at one and the same time. As they all cause a great deal of inconvenience, and some of them, as, for instance furuncles, often bring about the death of the patient, Ullmann's procedure merits a more extensive trial.

Notes and Comments.

Injections of Osmium Acid in Neuralgia.

In a meeting of the Petersburg Medical Society, Dr. B. M. Schapiro recently delivered a lecture on the treatment of neuralgia by subcutaneous injections of osmium acid (*St. Petersburg Med. Weekly Journal*, 26, 27, 1885). He first mentioned the observation of Fränkel, that the acid exerts a disturbing influence on the substance of the nerves and muscles, and greatly diminishes their activity. In nerves an epineuritis develops, which compresses the fibres, while in muscles an interstitial inflammation soon leads to atrophy of the muscular tissue. Living nerve-fibres assume under the influence of the drug a black tint, while the neighboring tissue becomes denser, and motor nerves situated near occasionally suffer decidedly in consequence of these injections, a fact to be well noted.

Dr. Schapiro studied the effect of the acid in eight cases of neuralgia of the fifth nerve. The pains attacked all branches of the nerve, and all cases were obstinate and of long duration. The result was a complete cure in five cases (62.5 per cent.), in two cases a decided improvement, and in one case no effect whatever. The two greatly improved cases were of the most violent and obstinate nature, and the want of success of the most severe therapeutical procedures warranted the belief that the nerves had undergone an incurable morbid change at their origin.

The following solution was employed by Schapiro for the purposes of the hypodermic medication:

℞.	Acidi osmici,	gr. $1\frac{2}{3}$.
	Aquæ destill.,	f℥jss.
	Glycerin. pur.,	f℥j.
M.	In vitro nigro.	

This solution, according to Schapiro, can be kept in a good condition from two to three weeks, a fact of importance if one takes into consideration the high price of the drug, while the simple watery solution is decomposed within a day or two. The number of injections in each individual case varied from one to twelve; in the beginning five drops, and later a slightly increased quantity were employed. In every case where the injection was made into the tissues directly over the seat of the pain perfect analgesia developed, but the pain occasionally then attacked neighboring branches of the same nerve, which before had not been painful. Other deleterious effects were never observed by Schapiro, only one lady, highly nervous and subject to epileptic fits, fainted immediately after the injection.

In cases where all other therapeutical procedures seem to be without effect, or where the intensity of the pain necessitates immediate relief, the hypodermic application of osmium acid may, therefore, well be worth a trial.

Healing by Faith.

We all know the power of imagination over bodily ailments, and in reference thereto we quote the following readable paragraph from *The Gentleman's Magazine:*

"There is the story of the French criminal who died because he believed he was being bled to death, while in reality his arm was only pricked, and a sound of trickling water made to imitate the noise of the blood flowing forth. In the same way it is recorded

how Mr. Loutherbourg cured large numbers of patients by attacking the imagination. Among those who had visited him was a man who had been troubled with great pains and swellings, particularly about the loins, so that he could not walk across the room. On entering, Mr. Loutherbourg looked steadfastly at him and said: 'I know your complaint: look at me.' They continued looking at each other some minutes; then Mr. Loutherbourg asked if he did not feel some warmth at his loins, whereupon the man replied that he did. 'Then you will feel in a few minutes much greater warmth.' After a short pause the man said: 'I feel as if a person were pouring boiling water over me.' Still looking in his face, Mr. Loutherbourg said: 'How did you come here, sir?' 'In a coach.' 'Then go and discharge your coach, and walk back to town.' The coach was discharged, and the patient walked back to town, and next day he walked five miles about town without fatigue. Similarly, Sydney Smith relates how the banker-poet Rogers caught a bad cold simply from imagining a window to be open, but which all the time was shut. It was at a dinner party, and the great sheet of plate-glass had deceived Rogers, who was sitting in what he thought to be a dangerous draught. To quote a further case: Dr. Sigmond relates how a poor woman, having applied to a physician for a cure of an affection of the breast, he gave her a prescription, which he directed should be applied to the breast. She returned at the end of a few days to offer her grateful thanks for the cure which he had effected; but on making inquiry as to the mode of action, he ascertained that his patient had very carefully tied the prescription round her neck. Faith cures of this kind are of constant occurrence, and we know how many persons, when suffering from maladies connected with the brain or nervous system, have been restored to their normal state of health by simple faith. Thus, startling effects have occasionally followed the swallowing of such make-believe remedies as pills composed of bread or sugar. This accounts, therefore, for the cures which were wrought in days gone by, even when medicine was in a backward state, and the most absurd prescriptions were often given to patients suffering from nervous diseases."

Treatment of Morphine Habit with Cocaine.

Against the morphine habit every known remedy has probably been recommended and turned out useless. But during the last six months a number of reliable observers have published the records of cases in which muriate of cocaine really seems to have had a very decided effect in subduing that intense restlessness, and that great increase of reflex excitabilty, which both are such characteristic symptoms in cases of withdrawal of the morphine in those accustomed to its use.

Dr. Jaeckel is the latest of these authors (*Deutsch. Med. Zeit.*, October 15, 1885). This article makes the impression of truth. He, like others recommending it, employs the muriate of cocaine by subcutaneous injection, but instead of using this remedy alone, he advises what to us appears a very judicious procedure, to add a small quantity of morphia to it. For instance, for every decigramme the patient was in the habit of using of the opium alkaloid daily, he employs a gramme of the cocaine during the whole treatment, and in the beginning he adds to it half the usual dose of morphia. Then day by day he slightly increases the dose of the cocaine, and lessens very materially that of the morphia. If a patient injected four times daily 10 grains of morphia (40 grains a day), 40 grains must suffice for the whole treatment. As a rule J. makes in such a case his injections also four times daily. He begins with about half a grain of the cocaine and 5 grains of the morphia the first day. The second day the dose of the cocaine is increased by $\frac{1}{6}$ of a grain, but that of the morphia is diminished to 3 grains. By the tenth day the morphia has been omitted, while about one grain of the cocaine is injected four times daily.

J. has not seen any specially agreeable sensation set in after a hypodermic of cocaine, but great rapidity of the pulse he has frequently observed as the direct consequence of it. He also insists that the patient must not only be treated at an institution, but that he should remain there for a considerable time after the total withdrawal of the drug. In his experience relapses are to be feared the less, the longer the patient was kept in the hospital.

Peculiar Case of Lead-poisoning.

Dr. Roberts Bartholow thus writes in the *New Orleans Med. and Surg. Jour.:*

When I looked at this man's swollen hand, outside, a few minutes ago, I was struck with the resemblance it presented to a case of plumbic rheumatism. For several weeks his hands have been swollen, as you see them, commencing in the right and extending to the left. The joints very much resemble the condition seen in lead-poisoning,

but when we inquire about his trade we learn that he is a shoemaker; now how could a shoemaker become poisoned by lead? When we inquire critically about the tools of his trade, we learn that the tacks which he uses are coated with lead, and that he is in the habit of keeping them in his mouth. When I look at the gums, I cannot say that I see a positive blue line, but they possess a bluish grey tint. These two facts and the absence of signs of any other diseased condition, incline me to the view that he is suffering from plumbism. In these doubtful cases, the correctness of the diagnosis can be determined by the results of treatment. The iodide and bromide of sodium both form soluble combinations with lead, while the bromide will also afford some relief to the uneasiness occasioned by the swelling. He will also take sulphuric acid lemonade, and the contents of his bowels will be kept soluble by sulphate of magnesia. The joints will be kept at rest, and, if he can afford it, he will take sulphur baths. If our diagnosis be correct, he will feel worse for a day or two, when he will commence to improve. In these doubtful cases we can often settle the question by urinary analysis, when if it be lead-poisoning we will find the salts of lead.

Extirpation of the Ovaries.

Duplay, in the *Arch. Gén. de Méd.*, Dec., 1885, gives his views concerning the removal of the ovaries for the cure of female complaints. He considers the operation indicated only in those cases where, in consequence of fibromyoma of the uterus, a continuous hemorrhage developed, which cannot be influenced by any other method of treatment. He reminds us of the well-known physiological fact, that menstruation is not possible without ovaries, and of the clinical observation that fibromyoma completely disappear, and the hemorrhage caused by them totally ceases as soon as the climacteric period has passed, and with it the menopause commenced, and contends that these facts justify the conclusion that cessation of the functions of the ovaries, induced by the removal of the latter, would bring about the same result.

In conclusion, Duplay reports two cases where, after the operation, which was performed for the purpose above-mentioned, all hemorrhage stopped. Regarding the statistics of this operation, as collected by Tissier, they show that of 170 women, in whom the ovaries were removed, 25 died in consequence of the operation—14.6 per cent. Of the 145 remaining 10 had no favorable result, the hemorrhages continuing with the same (in 10) or with less (in 3) intensity; in all the others (135) the hemorrhages did not return and the menopause set in. Although the influence of the operation upon the tumor is not mentioned in every case, in those where reference is made to it, the tumor had greatly diminished in size soon after the extirpation of the ovaries.

Duplay believes the operation to be indicated in all cases where other therapeutical procedures have been in vain, and where hysterectomy is either impossible or too dangerous. But for all fibromyoma, which are very large or in a state of cystic degeneration, he considers myomotomy the only operation promising any success and suitable for such cases.

Dry Dressings.

Before the Glasgow Medical Society, Mr. Maylard read a paper on this subject. After some observations on the value of bichloride of mercury as an antiseptic, the kinds of dressings employed were described. The ordinary requirements for any suitable case consisted of absorbent cotton-wool and Gamgee's tissue, both first saturated in a 1 to 1,000 solution of mercury, then dried, and a coarse muslin bandage. The cases suitable for the dressing were those where operation had been performed, in whom the wound would be aseptic from the first. The principles to be attended to referred both to the operation and to the after-treatment; in the former, it was needful to secure every bleeding point, to wash the wound well with a 1 to 1,000 bichloride, and then dry it as much as possible. The edges of the wound must be brought accurately together (where possible), and drainage effected by some easily-absorbed material; strands of carbolized gut in superficial wounds; Macewen's decalcified chicken-bone tubes in deep. In the latter dressing, iodoform was to be first dusted over, then a small pad of the prepared absorbent wool directly applied, and over this two layers of the impregnated Gamgee tissue. In applying the bandage, the edges of the dressing must be firmly secured, but only slight pressure produced upon the wound. In this method of dressing, air could freely permeate the bandage, tissue, and wool, so drying up the serous and bloody discharge, and keeping the part at a temperature equal to that of the other covered regions of the body. The dressing

should not be removed (supposing no untoward symptoms manifest themselves, which were unlikely if proper care were taken to render the wound perfectly aseptic from the first), until healing was supposed to have taken place. Cases were given illustrating the successful results of the treatment. Roughly compared with the ordinary Listerian dressing, it was calculated to be five or six times as cheap.

A Plea for Weighing Infants.

Dr. D. J. Viura y Carreras, medical officer of the children's department of a Barcelona hospital, has published some remarks on the importance of periodically weighing infants, by which observations it can be determined whether the mother's or nurse's milk is satisfactory in quantity and quality, and the desirability of a change is easily and early recognized. In the main, Dr. Viura agrees with the statements of Bouchut —viz., that an infant loses from 100 to 200 grammes in the first four to six days, regaining its original weight in seven days, from which time to five months it gains 25 grammes daily, being then double its original weight, and this is again doubled at sixteen months. He made a series of observations on his own child, and concurrently with them tested the mother's milk by Donné's lactoscope. The child was born on December 16, and on the seventh day weighed 3300 grammes. On January 15 it had gained 900 grammes; on February 2 there was a further rise of 800 grammes; but on March 1 the gain was only 500 grammes, the explanation being that the milk, which up to February 10 had had a density of from 23° to 28°, had in consequence of the appearance of the menses decreased in quality, having a density of from 30° to 35°. It afterwards recovered its former quality, and during March and April the child increased respectively 850 grammes and 800 grammes. It is of course necessary to take into account any pathological condition which may be present, and not to attribute to the nurse what may be due to syphilis or tuberculosis in the child.

Pleurisy with Effusion; Failure to Detect the Presence of Fluid; Death from Dyspnœa.

A man entered the Charity Hospital, New York, suffering from marked dyspnœa. Temperature 104°, pulse 120. The chest was examined in regard to the presence of fluid by auscultation and by means of an hypodermic needle, but no positive indication could be arrived at. The case continued for two days without much change, when death took place. To the surprise of all who had seen the case, both sides of the chest contained an abundance of fluid. There was also croupous pneumonia of the left upper lobe.

The critical reader of this report might feel disposed to reflect on the treatment of the case. If, however, he was at the bedside and found respiratory sounds over both sides of the chest, together with a pulse and temperature indicative of pneumonia (there was, as has been stated, pneumonia of the left upper lobe), and if he had inserted a hypodermic needle without result, it is quite possible that he would modify his original view.

In this connection it might be stated that some years ago a patient in one of the leading New York hospitals was under the diagnosis of pneumonia for a week, when he died. The chest in that case was filled with fluid. During life the patient was seen by a number of leading men. This latter case is referred to not for its novelty, but merely to indicate that the diagnosis of fluid is by no means easy.

The case that forms the subject of this report might be classed as one in which, from an error in diagnosis, the patient was permitted to suffer from extreme dyspnœa, and the lesson it teaches is that in cases of suspected pneumonia, with severe dyspnœa, extraordinary care should be taken in eliminating compression of the lung by fluid as a cause of dyspnœa. Reference has been made to the use of the hypodermic needle. The case reported here, as well as many other cases, conclusively prove that unless the hypodermic needle is of extra large size its use is very misleading and liable to favor an unfortunate error in diagnosis, as it did in the sad case here presented.

Sanitary Condition of Cairo.

From a foreign exchange we learn that scandalous as may be the administration of the Cairo Water Company, the disposal of the sewage is no better. The introduction of the luxury of water-closets, which always follows that of a public water-supply, has here as elsewhere greatly aggravated the evils of cess-pools in a loose sandy soil and in the midst of a crowded population. For those who more wisely adhere to a sort of pail-system, there is supposed to be a regular service of scavengers; but the sili set apart

for the reception of the excreta and their conversion into poudretti, is so difficult of access that the men employed by the sanitary authorities prefer to shoot the contents of the pails on an open piece of ground more conveniently situated within the city, or refuse to remove them at all, in which case the householders are driven to empty them into the roadway, where an absurd system of sweeping and watering carried on all day, instead of in the night, renders the streets almost unendurable, and the pedestrians are alternately blinded with dust or ankle-deep in mud. Ignorance and mismanagement characterize the present state of the medical and sanitary administration of Egypt; and we fear that nothing short of a dictatorship wielded by a man with the will and administrative power of a Bismarck would suffice to cleanse the Augean stable.

Case of Diabetes Insipidus (Specific Cerebral Disease).

Before the Manchester Medical Society, Mr. Coates showed a patient who had recovered from diabetes insipidus. The patient, a male, gave no history or previous symptom of syphilis, but he had an obstinate gonorrhœa(?) five years before. His illness began six months before he came under observation, with the passage of large quantities of urine (as much as two and a half gallons in the twenty-four hours), great thirst, severe headache, vomiting, and defective vision with the left eye. When first seen, the great headache confined him to his bed; he was passing between eight and ten pints of urine daily, and drinking an equal quantity of fluid, and he was almost blind with the left eye, without any obvious or ophthalmoscopic cause. The urine, which contained neither albumen nor sugar, had a specific gravity of 1002. The case was regarded as one of specific cerebral disease, and was treated with gradually increasing doses of iodide of potassium, and with mercurial inunctions. At the end of four months he was free from headache, the polyuria had disappeared, the specific gravity of his urine was 1012, the defective sight was gradually improving, he could walk about quite comfortably, and he felt as well as ever he had done before.

A Case of Chylous Urine.

In the *Indian Medical Gazette*, Dr. R. Temple reports the case of a man aged 37, who had made a journey of three days' march and upwards. The day after his arival he found "that his urine had turned to milk." The urine, of which a specimen was seen by the author half an hour after it had been passed, was normally acid, specific gravity 1017, color opaque, white, somewhat dirty-looking, odor natural. It had already become feebly coagulated throughout its mass. Urates, phosphates, and carbonates were present in normal amount, but no sugar. On boiling, three-fourths of the contents of the test tube became solid, and, besides albumen, there was some fat present. Under the microscope no filaria, no casts, were found; no blood corpuscles, and very few epithelium cells. There were numerous minute granular corpuscles, which seemed to be chyle corpuscles, as they were exactly like those in the molecular base of the chyle. The patient was allowed the diet which he preferred, and received 16 oz. bread, 12 oz. rice, 1 oz. sugar, ½ lb. mutton, ½ pint mutton soup, 1 oz. oil for cooking, 4 oz. vegetables, ½ oz. salt, and ½ oz. condiments daily, with water *ad libitum*. He was put on tr. ferri perchloridi, 20 minims in 2 oz. of water three times a day. The urine gradually returned to its natural appearance, and in three weeks he was discharged to duty, having gained three pounds in weight.

Case of Perforation of the Vermiform Appendix, followed by Acute Fæcal Abscess; Diffuse Peritonitis; Operation; Death.

In the *Brit. Med. Jour.*, February 27, Mr. Coates relates the case of a young woman who was suddenly seized with acute abdominal pains. These subsided, and she was able to resume her duties for twenty-four hours. The pain returned, being very severe on the right side of the abdomen; and, as she was constipated, powerful purgatives were freely administered by her friends. On the fifth day she was seen by Mr. Coates, who found her suffering from acute peritonitis, with tympanites and exaggerated pain over the cæcal region; she was very ill, and gradually became worse. The tympanitic bowel obscured any swelling in the right iliac region; but, a deeply-seated sense of resistance in that neighborhood daily becoming more marked, chloroform was administered on the ninth day. The existence of fæcal pus having been demonstrated by the aspirating cannula deep down underneath the distended bowel, a dissection was made, and about five ounces of fæcal pus were evacuated from a cavity around the cæcum, from the anterior of which a small stone was removed. The cavity had an opening into the peritoneum. It was thoroughly cleansed, and drainage-

tubes were inserted. After the operation, the acute symptoms were relieved; but the patient gradually sank, and died in twenty-four hours.

Case of Dystrophy of the Thumb-Joints.

Before the Medical Society of London, Dr. Maguire showed a patient, a young woman, who had lost the use to a great extent of the muscles of the thumbs in both hands, accompanied by grating, etc., in the metacarpo-phalangeal joints of those digits. She has never suffered from acute or chronic rheumatism, and the only other symptoms complained of were occasional headache, and pains of a vague character in the lower limbs. There had been no uterine troubles. All varieties of treatment had been tried, including the use of splints, without any manifest improvement.

Mr. Adams thought that the affection was probably not neurotic, inasmuch as there was little or no wasting; and advocated treatment by rest.

The President (Dr. Ord) said that this class of cases had interested him very much. His own opinion had been that this peculiar condition was caused not so much by direct nervous trouble as by irritation reflected from some part, such as the genital system.

A Case of Prolapse of the Rectum Treated with Sulph. Strychniæ Hypodermatically; Recovery.

Dr. S. A. Scott thus writes in the *New Orleans M. and S. Journal*:

In the summer of 1876 I was called to a child, aged 18 months, suffering with complete prolapse of the rectum. The bowel was swollen and looked as if it were bruised. I replaced it immediately, but found that the child could protrude it with almost as much force as it could extend the leg. I again replaced the gut, and, while an assistant held it in place, I injected $\frac{1}{30}$ grain sulph. strychnia into the sphincter ani; I then applied a wet compress.

After this the child had no further trouble, although it suffered with constipation several months after the above treatment.

I have had no opportunity of trying the remedy again, and publish this to the profession to see if the practice has been employed by other physicians, and with what success.

Inoculation of Tubercle.

From the *Medical Chronicle* we learn that at the Société Medicale des Hôpitaux, Paris, M. Merklen reported the case of a woman, aged 26, who, he believes, incurred a tubercular inoculation in the fingers from the clothes and sputum of her husband, whom she nursed assiduously for six months when he was suffering from phthisis. She had been previously healthy, and had no family history of tuberculosis. Two months after the death of her husband, small nodules appeared upon the index and middle fingers of her right hand. These were shortly followed by similar growths upon the anterior surface of the forearm. Lesions of the same character then appeared upon the backs of the hand and forearm. She suffered no pain, but began to emaciate, The lesions soon showed the characteristic appearance of cutaneous tubercle, and the bacillus of tubercle was found in them. Auscultation of the lungs revealed signs of infiltration, which M. Merklen believes to be due to a secondary tuberculosis arising from the inoculated parts.

Power of Infection of Old Gonorrhœa.

Neisser (German Medical Congress, in Strassburg) investigated 143 cases of gonorrhœa, which had existed for more than a year, in respect to their contagiousness. In more than half of these, the urethra had been irritated by repeated injections of 1:20,000 sublimate solutions. Quadrate heaps of gonococci were found in the pus, on staining with methyl blue; sometimes they were absent at several different examinations. Such cases as these would present but slight danger for an odd coitus, but would certainly be dangerous in marriage. Neisser can give no hard and fast rule about the infectiousness of chronic gonorrhœa; each case must be judged separately by special examination.

The most effectual treatment consists in the constant and regular injection, through a soft, thin catheter with multi-perforated head. of such solutions as arg. nit. 1:2,000—3,000, or sod. salicyl. five per cent. solution, with copaiva balsam internally to prevent cystitis.

Antiseptic Mouth-Wash.

Dr. Miller (*Deutsch. Med. Woch.*) found that, by using the following mixture, he could completely sterilize the mouth, cavities in carious teeth, etc.

℞.	Thymol,	4 gr.
	Benzoic acid,	45 gr.
	Tincture of eucalyptus,	3½ fl. dr.
	Water,	25 fl. oz.

The mouth is to be well rinsed with this

mixture, especially just before going to bed, since most of the damage by fermentative and putrefactive processes in the mouth is done at night, during sleep, unless the exciting cause be previously removed or rendered inert.

Primitive Endocarditis in Soldiers.

In a paper thus entitled, in the *Revue Médicale*, Fournier presents the following conclusions:

1. Primitive endocarditis, a very rare affection in the ordinary conditions of life, tends to become frequent in the military profession.

2. It is developed in this class under the influence of cold or of the fatigue of long marches.

3. It should be immediately opposed by energetic treatment in order to obviate the formation of fibrinous deposits.

4. The most advisable treatment consists in the application of wet cups to the cardiac region, followed by flying blisters. This treatment is followed by a very rapid amelioration of the condition.

Curious Position of a Supernumerary Tooth.

Dr. N. E. Foote thus writes to the *Dental Cosmos*: "A young lady of about sixteen years consulted me in January, complaining of her upper lip projecting, and being at times very sore. Upon examination I found the lip protruding considerably near the roots of the incisors, and apparently attached to the gum about their necks. Introducing a probe between the lip and gum, it came in contact with a hard substance. After separating the attachment between the lip and gum, I found a supernumerary tooth directly between the roots of the central incisors, and lying horizontally to them; the crown imbedded in the patient's lip. After pressing the lip up firmly, I removed the tooth. All her other teeth are in proper position."

Reward for the Discovery of a Substitute for Gum Senegal.

The Société Industrielle of Muhlhausen has announced a large nnmber of rewards, in the shape of various medals and sums of money, for the discovery of industrial improvements, chiefly relating to the textile industry. Among them is one which may possibly interest some of our readers.

A medal of honor and a prize of 5,000 francs is offered for the discovery of a substance suitable as a substitute for gum senegal in all of its applications, and costing less than the latter, which is now worth about 100 francs per 100 kilos.

Tubercular Infection Through Sexual Intercourse.

In the *Medical Times* Fernet points out the probability of tubercle being thus conveyed. Indolent blenorrhagic discharges in men, and certain forms of leucorrhœa in women, should be looked on with suspicion, and searched for the bacillus tuberculosis. Sexual intercourse with the subjects of genital tuberculosis should be avoided. In individuals affected with genital tuberculosis there is a risk of general auto-infection, and the tuberculous matter should be removed.

Relief of Gangrenous Breath by Means of an Inhaler.

At the Charity Hospital, New York, a case of phthisis, with gangrenous breath, was given an ordinary inhaler on which was placed a few drops of carbolic acid. Within a short time the breath ceased to be offensive, and much relief to the irritant cough was experienced. The inhaler here referred to was made of tin and covered. It was sufficiently large to include both mouth and nose.

News and Miscellany.

The "Royal Operation."

The *Cinn. Lancet and Clinic* tells us that Louis XIV. of France was the friend and patron of physicians; especially well did he support Dr. Francois Felix. Louis started in young with numerous doses of clap, then he had small-pox, measles, pneumonia, dyspepsia, finally to cap the climax, a perineal abscess and beautiful fistula in ano; then a carbuncle in the back of his neck, and chronic gout, then gravel, and finally died of a gangrene. All these evil afflictions kept his favorite doctor, Felix, busy. On Novemher 18, 1686, at Fontainbleau, Dr. Felix operated on the king for fistula, in the presence of Madame de Maintenon and a few other friends. The cure was marvelous, and so was the pay, for Louis XIV. presented his physician with a fee of $750,000 aud a farm. During various illnesses he paid Dr. Felix over five millions of dollars. The king having set the fashion of being operated on for fistula, most of the French nobility and the Parisian *demi monde* followed suit, and a brilliant historical writer of the period states that

"the nobility, male and female, flocked to Doctor Felix at Versailles, and no matter whether suffering from fissures or from hemorrhoids, presented their backsides to the surgeon, begging him to make a neat incision of the sphincter ani. More than thirty court ladies left in tears when they discovered they owned no real fistula." The operation in those days was called the "royal operation," and Doctor Felix reaped a harvest.

Hydrophobia in Paris.

There were, according to Dr. Dujardin-Beaumetz, nineteen deaths from hydrophobia in Paris last year, a number higher than in previous years; and the number of stray dogs destroyed was also higher, namely, 5,060. Of the 19 persons who died, 15 were males and 4 females. The youngest was a little girl aged 5½ years, the oldest a man aged 63. The time of incubation varied from 19 months (in the case of a young man aged 26) to 29 days (a child aged 11). In only one case was the time of the bite unknown. Excluding that, and the exceptional case of 19 months, an average of about two months is arrived at for the time of incubation. As to duration of the disease, the extreme limits were 1 day and 8 days, average 3½ days. In no case were the lower limbs bitten. In 12 cases out of 18, the upper members were bitten, especially the hand (9 times out of 13), the wrist 2. In the 6 other cases, it was the face (5 times) and the skull (1) that were attacked. Lastly, in 17 cases out of the 18, the bite was that of a dog; in the remaining 1, it was that of a cat.

Pimples on the Nose.

A correspondent of the *American Analyst* asks: "What is the cause of redness and pimples on the nose?" and receives the following answer: "Judging from the liquor saloon heading of your note and the *nom de plume* you have chosen, it is fair to presume that in your case rum is the cause, and medical men would call your disease dipsomania, and the skin disease acne, while in common parlance it is called 'rum blossoms.' The explanation is very simple. The circulation is through two sets of blood vessels, arteries and veins, both obtaining their motive power from the heart acting as a force-pump. Alcohol increases the pulsations, and as the blood is sent from the heart to the extremities faster than the veins can take it up again to return it, congestion results, and the nose, being at a remote portion of the circulation, reddens and finally becomes diseased. This, however, is not different from other organs of the body; all are congested and similarly diseased by alcohol. The best remedy is to discontinue the alcohol, and stimulate the absorption of the blood by the frequent application of cloths wrung out of hot water."

Amusing the Insane.

From the *Med. Record* we learn that praiseworthy efforts are being made at the Hudson River State Hospital for the Insane, to carry out the modern idea of keeping the insane patients occupied and amused. Statistics show that a very large majority are kept employed more or less of the time in work or amusement. One of the novel features is the establishment of a day-school which about sixty men and forty women attend. The efforts to secure musical entertainment have their humorous side. Dr. Atwood, one of the Assistant Physicians, in his report says: "An attempt was made to organize a band or orchestra, and six meetings of all patients and attendants possessing any musical ability were held in the amusement hall for rehearsal. The leader of the proposed band, however, having by this time run away, and the B-flat cornet becoming unusually disturbed, the drum and bass-horn were considered scarcely adequate in themselves to please the public, and the idea was postponed until our corps of employees is increased and we have our accommodations for the chronic insane."

Effect of 280,000 Pounds of Explosives 190 Miles Away.

A Boston special to the *Tribune* says: The jocose assertion of the first director of Harvard College Observatory, Professor William Bond, that the ponderous foundation stone on which the great refractor is poised could not be moved even by an earthquake has at last been disproved by observations taken there on the occasion of the recent explosion at Hell Gate. The method used by Prof. W. A. Rogers to develop the distance of vibration was the placing of a saucer of mercury on the solid cellar floor. In this mercury was a speck or flaw. Upon this point was brought to bear a microscope of 750 magnifying power, the spider line being in exact coincidence with the flaw. The first vibration perceived was about a thousandth of an inch, and recurred at intervals for nearly two minutes, the greatest

swaying of the mercury being over a space of one five-hundredth of an inch.

The air line distance between the Observatory and Hell Gate is nearly 190 miles. Accurate time was kept at both points. This explosion of 140 tons of the most powerful explosives, with the estimated lifting power of two and a quarter trillion pounds, is one of the greatest triumphs of science the world has ever known.

The Origin of the Montreal Epidemic of Small-pox.

The sub-committee appointed by the Civic Health Board to inquire into the origin of the late small-pox epidemic have submitted their report. From this we learn that previous to the beginning of 1885 there had been no small-pox in Montreal for several years. There is some disagreement as to the origin of the epidemic, but it seems probable that the disease was brought to Montreal from Chicago by an infected Pullman car conductor; that this man was admitted as a patient to the Hôtel Dieu, and not being carefully isolated, he communicated the disease to attendants and other patients, causing an epidemic in the hospital. The hospital was then closed, and the inmates leaving, distributed the disease through the city. The local health authorities are severely blamed by the Canada *Medical Record* for not having any provision for receiving and isolating small-pox patients.

The Decline in Cocaine.

The *Druggists' Circular* for March says that notwithstanding the fact that the consumption of cocaine is steadily on the increase, and that new uses for it are found every day, prices have declined rapidly, and even now there is a perceptible weakness about the market which forebodes lower values. The recent decline of nearly one-half, is owing principally to competition in its manufacture and the lower price of leaves. Cocaine has enemies, like other new articles, but in spite of them it has had an unprecedented growth. The market at present is quoted at about fifteen dollars by the ounce. Manufacturers are surprised, and characterize its sale as "something wonderful," as the demand is steadily increasing.

Artificial Eggs.

According to the daily papers a number of produce dealers in Paterson, N. J., were recently sold some artificial eggs. The fraud was discovered in time to have the man arrested under the adulterated food act. He pleaded guilty and was fined $50 and costs. He admitted to several dealers that the eggs were artificial, and were manufactured by a firm in New York, whose names he declined to disclose. The shells were made of a clear, translucent composition, and the shape was perfectly modeled. The portion surrounding the yolk was made of albumen, and the yolk itself of ground carrot and saffron. The eggs were tested and found to scramble well, and in an omelette there was no perceptible difference between the real and artificial eggs; but when boiled they are easily detected, as the yolk and surrounding white portion do not harden separately, as in the real egg.

The Charlatan's Advance Agent.

From the *Iowa State Medical Reporter* we learn that a prince among quacks recently hired a preacher, broken down physically and morally, to act as advance agent, under the guise of a horse-doctor. He learned all the symptoms of each chronic case in the section visited, and upon taking leave, wrote down the symptoms in the sufferer's own words. These records were given to his employer. When the patient came, he was only asked his name, and the impostor retired to consult the immortal gods about his patient. Upon re-entering, he heard, as if in his own words, the history and nature of his case. This was remarkable and mysterious, and showed the great physician to belong to a superior order of beings. This scheme was very successful, until the advance agent, failing to receive his share of the spoils, disclosed the plot.

Be Clean.

Professor Meandra is quoted by the New York *Medical Abstract* as follows: "Perhaps we do not understand the bacillus; he is the mighty leader of innumerable hosts, giving the law of cleanliness to all the world, and he stands ready with his inexorable hands to avenge his outraged rules. He laughs at the man who, hearing the distant rumble of the microbian drum, hastens to clean up his streets and prepare for a siege; but the bacillus wars not with streets, but with man, and man may have been for the previous ten years preparing in himself the soil, the battle-field, the NIDUS for his implacable foe. Banish each bacillus with the proper antizymotic, but if you would exterminate his race, be clean, *continually* clean."

Manual Training in the United States.

We are glad to note from an article in *Harper's Magazine* for February, 1886, by Mr. Charles H. Ham, that the progress of manual training in the United States during the last few years has been very great, whether it be considered from the standpoint of the growth of public sentiment on the subject, or from that of its introduction into existing schools, public and private, and the establishment of independent schools. It is in some form in certain of the schools in twenty-five States of the Union, and there are at least forty educational institutions in the country where it is made part of the course of instruction. The character of the schools into which manual training has been introduced is varied. The range is from the most noted colleges and universities in the land to the public schools of small cities.

To Distinguish Artificial Honey.

Artificial or adulterated honey, according to the *Industrie Blaetter*, is most easily detected by mixing with alcohol. A solution of 20 parts of honey in 60 parts of water when mixed with alcohol gives a heavy white precipitate of dextrin if glucose has been added, while natural honey under the same treatment only becomes milky. The safest way is to determine the grape sugar directly in a weighed quantity, boil an equal quantity in 2 per cent. sulphuric acid and determine sugar by inversion, and determine dextrin in third portion by precipitation with alcohol. The difference in amount of sugar found before and after inversion is so great as to afford a sure way of distinguishing natural from artificial honey.

Disinfectant Value of Stannous Chloride.

A. C. Abbott, M. D., of Baltimore, in the *Med. News*, reports experiments which show that stannous chloride, when in contact with spores in decomposing organic matter, kills them when it is present in the proportion of 1 per cent. after an exposure of two hours, but that it fails to disinfect the mass in the same time when the strength of the solution is reduced to 0.8 per cent. Zinc chloride was found to be active in 5 per cent., and inactive in 2.5 per cent. solution, while the sulphates of copper, zinc, and iron (ferric) were found to be inefficient respectively in 20 per cent., 40 per cent., and saturated solutions. Stannous chloride has the advantage over mercuric chloride in not attacking lead pipes, and in being much less poisonous.

Two Large Libraries.

The *National Druggist* informs us that the largest library in the world is the Bibliothéque National in Paris. founded by Louis XIV. It contains 1,400,000 volumes, 300,000 pamphlets, 175,000 manuscripts, 300,000 maps and charts, 150,000 coins and medals. The collection of engravings exceeds 1,300,000, contained in some 10,000 volumes. The portraits number about 100,000. The building which contains these treasures is situated on the Rue Richelieu. Its length is 540 feet, its breadth 130 feet. The largest library in New York is, in respect of separate works, the Astor. About 190,000 volumes are on the shelves.

Poisonous Honey.

At the last meeting of the Bee-keepers' Society in Dresden, Henry Bley, a pharmacist, brought forward the subject of poisonous honey, some, he claimed, having been imported from Trebizond (*Pharm Zeit.*, November 25, *Pharm. Jour.*, November 28). He attributed the noxious property to the growth of Datura Stramonium in the locality in which the honey was produced, and said that cases of sickness, in one instance followed by death, had been officially established. He also alleged, with what reason it does not appear, that some American honey has been found to contain poison derived especially from gelsemium.

Fraudulent Medicines.

Certain New York and Brooklyn druggists, according to recent reports, have been victimized by clever sharpers who offered for sale imitations of Wyeth's beef, wine, and iron, and other popular patent medicines. The goods were sold for less than schedule price, and upon examination the labels were discovered to contain numerous typographical errors, and, although the same in size, color, and type with those of the imitated preparation, were printed on inferior paper. Through the clever work of an amateur detective the fraudulent scheme was exposed. For more than eight months has this swindle been in successful operation.

Cleaning Powder for Windows.

A good cleaning powder for show-windows, which leaves no dirt in the joints, is prepared by moistening calcined magnesia with pure benzin, so that a mass is formed sufficiently moist to let a drop form when pressed. The mixture has to be preserved

in glass bottles with ground stoppers, in order to retain the easily volatile benzin. A little of the mixture is placed on a wad of cotton and applied to the glass plate. It may also be used for cleaning mirrors.

Cheaper Chloroform.

The manufacture of this article by a somewhat new process, in which alcohol is not employed, has very materially reduced the cost of production. Competition has consequently resulted in recent sales for export at 40 cents, and for home use at 45 cents per pound for one hundred pound lots. Lower prices are probable, unless the courts should decide that one manufacturer has a right to monopolize the process, in which event higher prices should be expected.

To Increase the Adhesive Properties of Plaster.

Dr. H. R. Kelly, of Galion, O., writes to the Cincinnati *Lancet-Clinic*, that a sponge, saturated with stronger ether, passed lightly over the surface of adhesive plaster, will cause it to stick firmly to the skin. No heat is necessary, and the plaster will adhere closely over the whole extent. Spirit of turpentine will act in the same way.

The Minister who Advertises Quacks.

Minister's wife (looking over the paper): "You are referred to in this morning's paper, my dear, as a distinguished clergyman."

Minister: "H'm! I thought that my sermon yesterday would attract attention. Is it published in full, or only a synopsis given?"

Wife: "Neither; you are spoken of as a 'distinguished clergyman' in connection with that patent medicine testimonial you sent Dr. Quack."

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDED MARCH 20, 1886.

Bailhache, P. H., surgeon. Detailed as Chairman Board of Examiners, March 15, 1886.

Fessenden, C. S. D., Surgeon. Detailed as member Board of Examiners, March 15, 1886.

Purviance, George, surgeon. Detailed as Recorder Board of Examiners, March 15, 1886.

Items.

—The preparation *Bromidia* has been introduced to the profession in England. Dr. W. W. Day, of Manchester, praises it as a tranquilizer of the nervous system.

—The Penna. R. R. will issue excursion tickets from Philadelphia to St. Louis and return for the American Medical Association, at the rate of one regular fare and a third, good for ten days from date of issue, $30.25.

—The Philadelphia Polyclinic and College for graduates in Medicine has established a hospital for operative and other cases at the college building, Broad and Lombard street, Philadelphia.

—A scientific society at Haarlem has offered a gold medal and 400 florins for the best treatise on the researches of M. Pasteur. The works, which may be in English, are to be sent in before April, 1887.

Dr. J. S. Jewell, of Chicago, is about to issue a monthly journal entitled *The Neurological Review*. Under his efficient management, it will undoubtedly take a position among the first-class periodicals devoted to that important specialty.

—Dr. G. S. Hill, of Wilmington, Ohio, reports in the *Lancet and Clinic* that he has employed Listerine hypodermically in malarial diseases with what appeared to be favorable effects. No unpleasant symptoms followed its use.

—It is reported that proceedings are about to be instituted in Germany against a number of persons styling themselves "doctor" on the strength of diplomas purchased from America *in absentiâ*. In Berlin alone there are said to be 3,400 of these "doctors," either of medicine, philosophy, or law.

A medical man who has lived a long time among the Chinese writes that they treat cholera by acupuncture and cauterization. They believe that the poison accumulates in certain parts of the body, and can be discovered by an adroit physician and extracted; it is of practical value, as the pains accompanying the cramps are immediately relieved by acupuncture.

QUERIES AND REPLIES.

Dr. W. C. E., of Minn., asks suggestions for the treatment of two obstinate cases of pruritus around the anus. No hemorrhoids or other complications. The subjects are healthy men in the prime of life.

Dr. K., of Mo.—Several hotels remain open in the Adirondack mountains during the winter for the accommodation of invalids, but we do not know their addresses.

Pallas Syringe." The most useful Instrument for Vaginal Medication and Irrigation.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

15155605-

IMPERFECT HEARING AND THE HYGIENE OF THE EAR.

Including Nervous Symptoms, Tinnitus Aurium (or Noises in the Ear), Aural Vertigo (or Dizziness), Diseases of the Nose, Throat, Middle Ear, and Mastoid Region. With the Mode of Instructing the Deaf-Mute at Home.

By LAURENCE TURNBULL, M. D., Ph. G.,

Aural Surgeon to the Jefferson Medical Hospital and Howard Hospital, Philadelphia.

Third Edition. With Illustrations. 147 Pages. Large 8vo. Extra Cloth. $2.50.

"That this book has reached a third edition is good testimony of its value and general excellence. We recommend it cordially to all those who are interested in the subject of which it treats."—*Glasgow Medical Journal.*

"On all the subjects treated Dr. Turnbull has much to say that would interest the specialist as well as the general practitioner."—*American Journal of the Medical Sciences.*

"The pages of this book are stores filled with valuable treasures, for the topics under discussion are of the highest interest, scientifically and practically, and no intelligent physician can afford to be ignorant of them."—*Chicago Medical Journal and Examiner.*

EPITHELIOMA OF THE TONGUE—CAPITAL OPERATION NECESSITATED BY AN APPARENTLY SLIGHT INJURY.*

BY WILLIAM HUNT, M. D.,

Of Philadelphia.

Clinical experience often destroys theoretical teachings. Here is a case that I think admirably illustrates that the original sore in cancer is not a purely local lesion.

The patient is a man aged 50 years, from whom one year ago we removed an epithelioma of the lip, only three months after the trouble began.

To-day he presents himself with extensive carcinomatous disease of the tongue, which involves the submaxillary glands as well as the inferior maxilla, rendering it impossible to operate. The patient says that for years he has smoked clay pipes. This is undoubtedly an irritant, but if it were in itself a *cause* of this disease, we would have arrayed before us an unending line of cancer patients, while observation proves the disease is as prevalent among those who never use tobacco as among old smokers. This man complains of no pain in the tongue, but the act of swallowing is becoming difficult and painful; it is only a question of time with him. There was in this case no history of hereditary taint, and the initial sore was promptly removed; yet he returns in one year with a reappearance of the disease, showing by the condition of the neighboring lymphatic gland that the disease is constitutional.

I repeat that the case serves to illustrate the fact that this disease (of which the *mildest* form is epithelioma) is primarily something more than a local lesion.

CAPITAL OPERATION NECESSITATED BY AN APPARENTLY SLIGHT INJURY.

The patient is a young man, who three weeks ago lost the little finger of his left hand in consequence of a heavy weight falling upon it. The finger was immediately amputated by the surgeon who was called in at the time, and the injury seemed a comparatively trivial one to both the doctor and patient.

Owing to the peculiar anatomy of the extensor tendons of the fingers, any severe injury done to the ring or little fingers is more apt to be followed by destructive inflammation of the hand from cellulitis, and the formation of abscess, than if either of the other fingers or thumb be so injured. Here is a good illustration. This man's injuries were thought slight, yet to-day—only three weeks after the accident—he comes before us in a half-dead condition. His arm is frightfully swollen and fairly riddled with abscesses; but this is not all, he is almost exsanguineous from the severe secondary hemorrhages he has suffered. His one only chance is in removal of the disorganized member, and yet he is almost lifeless from loss of blood, rendering the administration of an anæsthetic exceedingly dangerous.

Before beginning with ether, we gave him to drink one-half ounce of brandy, and the assistant watched his condition very carefully. During the operation his pulse rose to 140,

* Abstract of Lecture delivered at the Pennsylvania Hospital.

and at intervals of ten minutes we administered hypodermically small quantities of brandy. The arm was removed a little below the elbow-joint. Every means of restoration was resorted to, and the patient carefully watched; toward the afternoon he showed signs of sinking, and for twenty-four hours succeeding the operation his condition was a very critical one, but we had the pleasure of seeing him make a complete recovery after this, what we call, prime operation. The patient is doing well in every respect.

Communications.

THE SIGNIFICANCE OF SPECKS OR OPACITIES BEFORE THE EYES.

BY T. C. RILEY, M. D.,

Of New York.

Any and all subjective symptoms denoting ocular disturbance are naturally alarming to even the most callous nature, for upon the integrity of the eyes depends in great measure the ability to perform the daily requirements of life in whatsoever sphere an individual may move.

The impairment of sight, though even temporarily, necessitates an abridgment of routine occupation, whatever its nature.

The child at school is thereby prevented from the pursuance of studies, to the possible detriment of future mental advancement. To the active man of business visual defects, be they functional or organic, are of sufficient import to cause him a sense of uneasiness at least, if not considerable alarm. The relative import of specks or opacities floating before the eyes may be regarded as dependent upon their nature, their situation, and their persistency. Provided the nature of the speck is such that its removal can be readily accomplished, the significance of its presence consequently is not of serious import.

On the other hand, in case the foreign body or speck is beyond easy reach, then its removal comes within the domain of surgical or operative interference, and its disestablishment is fraught with greater danger, and its significance, therefore, considerably augmented.

The existence of specks before the eyes may assume a temporarily recurrent or a permanent character. Either of these conditions may also be of a benign or serious nature, depending upon their cause and the amount of injury done to the structures with which they come in contact.

SPECKS BEFORE THE EYES NOT ADHERENT TO THE EYEBALL.

Such may consist of eye-lashes or the longer hairs of the brow hanging over the palpebral opening and coming more or less frequently within the field of vision. Again, particles of woolen fibre from the clothing or bits of extraneous matter of any kind floating in the atmosphere may adhere to the lashes or become mingled with the conjunctival secretions, and as they are moved by the closing and opening of the lids over the pupillary space, produce the sensation of a foreign body flitting before the eye. Shreds of mucus, the product of an inflammation of the lining membrane of the lids (conjunctivitis) are often productive of much annoyance, and in a similar manner.

Some years since a lady whom the writer was attending became most intensely alarmed under similar provocation as above described. As she expressed it, she seemed to see what appeared to be worms constantly passing and repassing before her eyes. Some appeared quite large and occupied considerable time in transit, while others, apparently smaller, proceeded more rapidly across the visual field.

The same patient, retiring one night after having knitted with red-colored wool during the evening, found upon awakening the next morning and looking in the mirror, that her face in the immediate vicinity of the affected eye was evidently smeared with blood. The latter condition was due not to nocturnal hemorrhage, as both she and her husband supposed, but to particles of wool fibre which had been carried to the eye on the fingers in the endeavor to appease, by rubbing, the itching experienced during the night. It required considerable effort, however, to satisfy her that such was the case; but I was ultimately successful, as a close inspection of the inner surfaces of the eye-lids revealed small masses of colored fibre which, upon being transferred to the microscopic slide, demonstrated beyond peradventure the correctness of my diagnosis as to the ætiology of the supposed hemorrhage. Thus it is that many curious and perhaps startling phenomena are capable of easy solution.

FOREIGN BODIES UPON THE CORNEA ACTING AS OPACITIES.

Such must be adherent to the cornea at a point sufficiently near its centre to extend with entirety or in part over the margin of the pupil, in order to be seen by the eye on whose

surface they lie. Under such circumstances the annoyance is commonly constant, unless it be of recent occurrence, when the pain and lachrymation consequent upon its presence practically necessitates a suspension of the visual functions. Inspection with or without oblique illumination is ordinarily sufficient to determine the existence of such specks, and their speedy removal will terminate the consequent annoyance their presence engendered.

A foreign particle, as a piece of stone or steel, may lodge upon the cornea at a point sufficiently near its margin to be to the outside of the pupillary circle under ordinary circumstances, while in a duller illumination, with the consequent dilatation of the pupil, it becomes, in part at least, situated within the margin of the same, and is, therefore, liable to be noticed and to constitute itself a source of annoyance under such conditions. Opacities of the cornea, the result of previous inflammatory action, are not unlikely to prove annoying, as they produce a sense of a film before the eyes. Their presence is discoverable by inspection, and when found they should be treated according to circumstances, depending upon their cause, duration, and present appearance.

OPACITIES OF THE LENS APPEARING AS SPECKS.

Opacities of the lens, if not confined to its periphery, are certain to appear in the line of direct vision at times if not constantly, and necessarily move with the movements of the eye-ball. They may appear as single or as multiple opacities, and possibly involve the whole lenticular substance eventually, which condition is known as cataract. Vision under such circumstances is reduced to a minimum.

The consideration of the significance of such specks, belonging as it does to the subject of cataract, is purposely omitted here. Particles that are adherent to a certain point, either upon the surface of the eye-ball or within its substance, move with the movement of the eye, and will, therefore, always appear in the same relative position, whereas free or non-adherent particles assume different phases as to size, shape, and location under various circumstances.

FREE OR FLOATING SPECKS THAT EXIST WITHIN THE EYEBALL.

Free or non-adherent specks, or floating opacities, as they are generally designated, are of quite common occurrence, and depend for their causation and existence upon various conditions. Particles entering the eye by force from without commonly become imbedded and are held in position by the stroma of the tissue upon which they rest, and remain so unless enticed out by mechanical means, such for instance as steel chips by the aid of the magnet. Various conditions of the system permit of the formation of floating specks, especially the inflammatory processes which the different component structures of the eye are liable to undergo, singly or collectively.

IRITIS (AN INFLAMMATION OF THE MUSCLE SURROUNDING THE PUPIL) AS A FACTOR IN THE PRODUCTION OF SPECKS.

During an inflammatory condition of the iris deposits of fibrin may occur upon the posterior surface of the cornea, provided the iris bulges forward sufficiently to come in contact with this membrane; or upon the anterior capsule of the lens, if the inflamed muscle happen to fall upon this structure; and these deposits, until removed by absorption, produce the sensation of specks before the eyes. Again, slight hemorrhages from the blood-vessels of the affected structure flowing into the watery fluid contained in the front part of the eye-ball (aqueous humor) give rise to a similar condition, which, under favorable circumstances, disintegrate and are carried off by the absorbents after a short period.

An apoplexy of any vessel that permits of an extravasation of blood into either the anterior or posterior chamber of the eye will produce the same effect as the foregoing, the significance of the anomaly depending entirely upon the nature and cause of the hemorrhage, the prospect of its repetition and the facility with which it becomes removed by absorption. The more serious lesions manifesting the subjective symptom under consideration with which we are called upon to deal are only determined by ophthalmoscopic examination, and involve the deeper structures of the globe of the eye.

Apoplexies of the ciliary body, the retina, and choroid coats are prolific causes of specks floating before the sight; and, in consequence of the delicacy of these structures and the facility with which they may become destroyed, the significance of such phenomena due to these causes becomes at times a matter of considerable gravity. The appearance of specks thus originated often assumes an infinite variety of shapes and phases, and may be either temporarily recurrent or quite permanent. If due to an hemorrhage within the eye, provided no *serious* injury is done to

the internal coats of the structure, the opacities are ordinarily removed by absorption within a short period, when the sight regains its normal acuity. However, hemorrhages of the retinal and choroidal vessels are exceptionally recovered from without some, though in some instances slight, organic changes resulting, which, provided the lesion occurred at a point sufficiently near to or upon the macula, may preclude the possibility of complete restoration of visual perception. The point of origin and location of specks, such as has been referred to as existing within the interior of the eye, can only be determined by careful ophthalmoscopic investigation, which will lead to the application of proper therapeutic measures for their removal, as well as for the prevention of subsequent developments of a similar nature.

Certain conditions, notably gout and rheumatism, are frequently productive of opacities within the eye, as by fulfilling the necessities of the nature of such diseases they develop within the structure of the walls of the blood-vessels a condition of friability quite conducive to an hemorrhagic tendency. Opacities existing in conjunction with either or both of these diseases often evince a disposition to resist ordinary treatment for their removal, and the patience of the physician is greatly taxed, perhaps before his efforts are crowned with success. Knowing that with such patients the absorbing powers of the system are impaired as well as the excretory functions generally, it is frequently necessary to resort to active stimulation of the latter in order to prepare the former for the demands to be made upon them. The urine of such patients should be very carefully examined, and frequently, to enable us to ascertain with the utmost precision the exact conditions with which we have to deal. Attention of an hygienic and dietary nature is also of importance, as a proper regimen diligently pursued under these heads will often lead to most happy results after the continuous exhibition of drugs has proven inefficacious. Therapeutic measures of a medicinal nature may be resorted to according to existing circumstances for as the eye trouble in most cases of this nature depends upon the general systemic disturbance it is best remedied by combating the individual diathetic tendencies, at their inception if possible, while at the same time endeavoring to dethrone and overcome them when found to be established. The relation that the general system bears to the eye and other organs of special sense should not be lost sight of, for by such neglect on the part of the physician, the best reparative results desired cannot be expected to attend on our efforts no matter how excellent the special therapy resorted to.

105 *Madison Ave.*

MEMBRANOUS CROUP.

BY J. A. De ARMOND, M. D.,

Of Le Claire, Iowa.

In the Reporter of Feb. 27, Dr. Cowell reports two cases of the above-named disease which are exceptionally interesting, since the treatment followed, although unsuccessful, was energetic and rigid, and it seems to me established some tangible points in the treatment of this dread disease. In the first of the cases recorded the facts briefly stated are these: An eleven-year-old patient was attacked with croup. Vigorous treatment was begun on the 12th of the month, and continued until the 18th of the same month. During this time about six hundred grains of calomel were given. At the end of the time the membrane was finally cast off, having re-formed several times. Then follow some complications which we at present will not examine.

The great mortality of all known treatments of membranous croup has stimulated medical men the world over to desperate endeavor to discover, if possible, some line of treatment that would in some measure abridge the fearful mortality of the disease. Almost uniform failure has not disheartened nor discouraged the anxious inquirers after knowledge, and the reports that find place from time to time in the multitudinous medical journals of the day show that if a specific is not finally found it will not be for want of patient and faithful effort.

Among the remedies that have for many generations stood the criticism of failure and the praise of occasional success, calomel certainly stands at the head. In the years that are long since but memories, when calomel was the cure-all, it found its claimants for success in the treatment of croup. Now when it has been supplanted by more modern drugs in the treatment of many affections for which it was once regarded as next to a specific, it still has its able defenders as the most powerful of our armament in croup. Physiologically considered, it increases the secretions and exerts very marked control over serous inflammations. Large doses, however, lower the nutrition and destroy the crasis of the blood. The large doses that were once the common rule

in the use of this drug found favor probably in the popular belief that you can't get too much of a good thing. Whatever foundation this belief may have in the financial world is no argument that any measure of truth attaches to it in the world of medicine. The fact that a certain effect is produced by a certain dose is not any reason for believing that a very greatly increased effect for good will be secured by the exhibition of a dose fifty times as large. The enormous doses that once formed and occasionally still form the domestic panacea have made and are making dentistry a paying lead, while the amount of the remedy that has been utilized only in the imagination of the taker is certainly enormous. To take only the amount of a remedy which will in the shortest space of time bring the system under its influence and at the same time not derange the system, is certainly the correct plan. To overpower the system is not the best way to test a remedy's curative effects. It is always poor therapeutics that will necessitate the correcting of treatment, or rather the treating of treatment, if I may be allowed the expression.

To intelligently approach a case of croup means more than appears on the surface. Croup is a disease that takes life in two ways. First, and generally, it chokes the child to death. That is, it prevents the proper æration of the blood. The accumulated impurities which can not be got out of the blood finally poison the system, and death comes, preceded by the general muscular relaxation which is incident to a partial loss of nervous control over the muscular system. Second, the child is worn out by labored respiration, the loss of strength incident to the dislodgment of repeated forming of membrane. Then the treatment of croup means three things:

1. The dislodgment of the membrane.
2. The prevention of its re-formation.
3. The husbanding of the strength.

These three requisites are rounds in the ladder that lead to success in the treatment of croup. To omit or neglect any one is to drop out a round, and so weaken the ladder and thereby lessen the chances of recovery. In no treatment with which I am familiar is there an omission of emetics. Emetics, I am well satisfied, very often do harm, and the reader can easily see how and why this may be. Nevertheless, the judicious and careful employment of emetics is a powerful factor in the successful treatment of this disease. A rule to which I have never seen an exception is that depressing emetics are never to be used. By the timely use of emetics an amount of relaxation and an increased secretion of mucus are obtained that are at once surprising and gratifying. A remedy that secures the latter effect, to a remarkable extent, is the muriate of pilocarpine. It is a drug that has hardly been tested sufficiently yet to warrant its being assigned to a fixed place among the remedies for the treatment of croup; but I am well satisfied that it will not disappoint those who give it a fair trial. In the limited number of cases in which I have used it, I found it of most excellent service. Tonics, preferably quinia, are always indicated sooner or later, and generally at the outset. The disease always tests the strength, and to apprehend an enemy is to thwart his designs. It frequently happens that a troublesome cough is present, due to a hyperæsthesia of the laryngeal surface. Nothing relieves this so thoroughly as opium, and a fine combination is Dover's powder, and with it may be combined a small dose of calomel. Inhalations of lime-water, iodine, vinegar, and other substances, vaporized by an atomizer or by means of hot water, hold a place that none would care to dispute. It is not much wonder that when the question of pathology, not to say morbid anatomy of the disease, is not a matter of settled conviction, there should be so much dispute as to lines of treatment.

To my mind, Dr. Carrell has demonstrated beyond a reasonable doubt, that croup cannot be cured by the heroic use of calomel. Despite the fact that both his cases lived long enough to thoroughly test the efficacy of the drug, yet in neither was its use followed by the symptoms that should encourage a repetition of the trial. The fact that no diarrhœa followed the exhibition of such doses, would rather indicate that little of it was absorbed, and that the great bulk was simply lost. All in all, I regard the doctor's cases as most interesting—interesting despite the fact that he failed, and because he tested a remedy faithfully, and in the end found it not sterling.

The tendency, finally, in all cases, without exception, is to throw off the membrane if life be sufficiently prolonged. The membrane is not so formed as to live as a growth lives, but sooner or later a line of demarcation separates it from the inflamed mucous membrane, and then is the time that dislodgment is possible and easy. It doubtless frequently happens that the particular drug used at the time of separation, and not deserving nature, gets the credit. If life can be maintained for three to six days, I am

satisfied that nature will displace the membrane; but it may at once re-form.

I would not detract in the least from Dr. Carrell's credit, for he is entitled to all the credit that can belong to honest endeavor, but I think the day for the heroic use of calomel is past.

NOTE ON THE USE OF LANOLIN IN THE OPHTHALMIC PRACTICE.

BY M. LANDESBERG, A. M., M. D.,
Of New York.

Lanolin, a compound of cholesterin-fat and water (30 per cent.), which has lately been recommended by Liebreich as a new base for ointments, is the product of the natural sheep's wool fat, and presents a perfectly neutral substance, which will neither decompose nor ever become rancid. It far surpasses all other fatty matters and cosmoline preparations by its high capacity of being absorbed by the skin, which gives it at once the preëminence of all other vehicles for ointments, which have been used until now. The superiority over cosmoline as a base for eye ointments I can attest by my own experiments, having exclusively used lanolin for the last two months in all instances in which I had formerly resorted to cosmoline. The lanolin ointment being more consistent than the cosmoline ointment does not melt so easily when applied to the eyeball, and is for this very reason more pronounced in its topical action. It can be rubbed in so completely that hardly any fatty gloss remains to show the application, without irritating in the least even the most sensitive eye. As the capacity of lanolin for water is very great, any residue or surplus of the ointment can easily be removed from the eye by subsequent irrigation. Druggists highly praise lanolin for its property to combine more thoroughly than any other vehicle with the medicaments by which they are enabled to compound an ointment which for homogeneity will answer the most idealistic expectations. Besides for eye ointments, I have used lanolin as a vehicle for ointments with zinc, belladonna, aconite, veratria, and oleate of mercury, the latter of which I almost exclusively use in my private practice instead of the mercurial ointment for inunctions. The superiority of lanolin over all other vehicles in these instances has also been proved in these experiments. The only caution we have to take is to prescribe smaller doses of heroic remedies for ointments with lanolin, as the latter, as it had been stated above, is so readily and completely absorbed by the skin.

MEDICO-LEGAL CASES.

BY HENRY A. RILEY, ESQ.,
Of New York City.

The Supreme Court of New York, sitting at the city of Brooklyn, has recently been trying with great vigor a tomato case. It was brought by Miss Theodora Kalyer against the large provision firm of Thurber & Co., for $50,000 damages for injuries claimed to have been suffered by eating canned tomatoes sold by the defendants to a grocer in Brooklyn, who sold them to the plaintiff. It was alleged that the plaintiff was poisoned by the use of muriate of zinc in the tops of the cans. Both sides had many experts present, and the case occupied the attention of the court for about two weeks.

It appeared that the tomatoes were not canned by Thurber & Co., but by Shade & Johnson, a Maryland firm, and the question was whether Thurber & Co. were liable for any improper packing of the tomatoes by them. There was some little evidence which might be claimed, the judge said, to throw upon Thurber & Co. a knowledge of the use of the muriate of zinc by the original packers. Otherwise, if any harm happened, the firm of Thurber & Co. would have no knowledge at all of the improper packing, and would not be liable.

The evidence was not considered by the jury as strong enough to impose any liability upon the defendants, and a verdict was given in their favor. It is said that no other instance of harm from the use of this brand of canned tomatoes has been made public.

The perils of the physician who honestly tries to do his duty by his patients, from blackmailing suits, are well known to our readers from the frequent mention made of such actions in the daily papers. That the volunteer nurse who, from friendship, offers to sit up at night with a sick man, should run the same risks, is a decidedly new experience. Such a suit has, however, been brought in the New York Supreme Court by a widow, who claims that the death of her husband was caused by the careless and negligent treatment of a friend who watched one night by the sick man's bedside.

The defendant naturally denies the liability, and says that the sick man expressed himself as well satisfied with the treatment given.

One of the recent cremations at the Fresh Pond Crematory, near New York, was that of Charles Cohn, a writer connected with the German press of New York. He stated in his will that he wanted his "body cremated without ceremonies, and in the simplest and least expensive way. The ashes I wish either to be sprinkled around a tree or on a garden spot, where the rains may mix my remains with the soil, or the winds disperse them." The executor, Dr. Rudolph Frankel, carried out the wishes of the deceased, so far as the cremation was concerned, but declined to scatter the ashes. He will send them to the sister of the dead man, who lives in Breslau, Germany. Mr. Cohn left the income of his property to his sister, and after her death it was to be divided into 100 shares, most of which are given to charitable institutions. On the envelope containing the will were the words, "My congratulations to my heirs."

The Lord Chancellor of England has presented to Parliament two important bills relating to lunacy proceedings. The first is said to be one of the bulkiest bills ever introduced into Parliament, and consists of 355 different sections, besides forms and schedules. It is in fact a codification of all the existing English statutes into one comprehensive and intelligent law.

The second bill, called the Lunacy Acts Amendment Bill, is an important one, and aims to place further safeguards around the commitment of lunatics. The medical certificate of any "interested person" is particularly forbidden to be used.

Lunacy legislation is becoming everywhere more favorable to the unfortunate patient, and it is to be hoped that instances of injustice will soon become impossible when the law is properly enforced.

In a recent French case, a dentist was sued for damages resulting from the death of a patient through the use of an anæsthetic. The court held that the dentist was neither a physician nor a health officer, and could not legally administer the anæsthetic. He was adjudged guilty of manslaughter, but the punishment imposed was only a fine of 3600 francs.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Thursday, February 4, 1886. The President, B. F. Baer, M. D., in the chair.

Cases of Laceration of the Cervix Uteri, with Unique Symptoms.

By Dr. Chas. Meigs Wilson.

The histories of the following cases are brought before the Society in order, first, to record what the writer believes to be unique symptoms of the lesion, and secondly, to elicit discussion in reference to the reflex nervous symptoms of the lesion, and, if possible, to draw the line of demarcation between them and the nervous phenomena of alienation. But a few years back we were given the doctrine, *ex cathedra*, that lack of contour of the cervix uteri was the principal cause of that train of nervous symptoms, of which histories here cited contain unique examples. Prior to this the clitoris was supposed to be the source of all the trouble. And now that spraying has become the fashionable surgical procedure, the ovaries have been given the precedence in the causation of the grave reflex nervous symptoms attendant upon pathological conditions of the pelvic viscera. Statistics have pretty well proven that in a large majority of cases destruction of the natural contour of the cervix has been the starting-point of pelvic distress in a large number of such cases. The subinvolution, with the subsequent conditions of prolapsus, hyperemia, hypergenesis of tissue, ectropion of the cervical mucosa, and the inflammation set up by friction of the everted cervical mucous membrane against the posterior vaginal wall, which frequently occurs in neglected cases of laceration of the cervix, are undoubtedly the primary factors of pelvic irritation in many cases, and it is easy to see how this condition may set up pathological conditions of uterus, fallopian tubes, and ovaries secondarily. To say precisely what is to blame is a very difficult matter. The following cases are selected from a large number operated upon by Dr. E. Wilson in private practice, and by the author in the surgical wards of the Philadelphia Lying-in Hospital:

Case 1. Mrs. McF., æt. 32, married, mother of three children, presented herself at the clinic of the Lying-in Charity with the following symptoms: For the past year she had noticed a tumor about the size of a small fœtal head in the right lumbar and the right half of the umbilical region. The tumor was perfectly smooth, non-nodulated, and freely movable in the abdomen. She had had obstinate constipation, a good deal of vesical irritation; at one time had had a sanguined purulent discharge from the vagina; this had entirely ceased for the last seven months. She complained of deep-

seated, darting pains in the lower part of the abdomen, backache, intense cephalalgia, and photophobia. Her last child had been delivered fourteen months previously with instruments. She had been under the care of a prominent gynecologist, who had diagnosticated floating kidney and recommended extirpation. After a careful examination, in which I was aided by several professional friends, the diagnosis previously made was concurred in. A careful chemical and microscopical examination of the urine failed to detect any abnormal constituent. It was then determined that laparotomy for removal of the kidney, or cutting down upon it and stitching in proper situ, would be alike unjustifiable. Upon making a more careful examination, including the uterus, the patient was found to have an extensive bilateral laceration of the cervix. The contour of the cervix was restored; and, although the patient still has her floating kidney, all her distressing symptoms have ceased.

Case 2. Mrs. S., æt. 32, married, mother of two children; pelvis slightly contracted antero-posteriorly. Both children were delivered alive by forceps. This patient was sent me by her regular attendant, with the diagnosis of cancer of the rectum. She suffered greatly from backache and headache, was constipated, passed ribbon stools, and had agonizing pain upon defecation. She had slight vaginal discharge, and a coffee-colored, foul-smelling, muco-purulent discharge from the rectum. Rectal examination revealed an ulcerated surface extending apparently for about an inch and a half in length completely around the rectum, about three inches above the anus. Small portions of the granular surfaces of the ulcer revealed under the microscope no evidence of malignant growth. Specular examination of the vagina showed extensive bilateral laceration with acute retroflexion. This woman presented no evidence of cachexia. The uterus, though closely bound down by adhesions, was finally restored to its proper axis. After several weeks the contour of the cervix was reformed. Simple astringent applications were made four or five times to the rectal ulcer. The patient made a complete recovery, and has had no return of symptoms since the operation.

Case 3. Mrs. C., æt. 22, mother of one child, with history of tedious instrumental labor. This patient suffered from violent ovarian neuralgia, augmented at the catamenial periods, She had a profuse leucorrhœa, engorged uterus, and enlargement of the right ovary. She also suffered at times from suicidal dementia, which was sometimes so violent that she required restraint. Her case had been diagnosticated pyo-salpinx and oöphorectomy advised. Examination revealed an extensive bilateral laceration of the cervix, extending on the left side to the vaginal junction. The cervix was restored, with complete cessation of all symptoms. Examination six months after the operation failed to find tenderness or enlargement of the right ovary.

Case 4. Mrs. S., æt. 37, married, mother of five children. This patient had been incarcerated in a private asylum for fourteen months, suffering with violent dementia. She had the typical appearance of alienation. No clear history could be obtained of her symptoms excepting that she had distressing pelvic pain and profuse leucorrhœa. Examination showed extensive laceration of the cervix. Trachelorraphy was performed, with immediate amelioration of the symptoms. Two months after the operation she was restored to her family completely well. A year or more has elapsed since the operation, in each of the cases, and the relief afforded has thus far been permanent. These cases appear to the author to have had unique symptoms, following and consequent upon the lesion, though doubtless those with more extended chances of observation have met with cases presenting analogous symptoms.

Dr. Joseph Price made some remarks upon the effects of cicatricial tissue in the edges and at the apex of the laceration, of the effect of the laceration in inducing local engorgement and hypertrophy, and thus a long series of consequential symptoms. He spoke of the value of rest and local treatment for the relief of these symptoms, but the relief so obtained is temporary; it will last but a few months, and sooner or later, after the patient is discharged as cured, the same symptoms recur. If the cicatricial tissue is not all removed and complete union secured throughout the entire thickess of the cervical tissue, the symptoms will return or even be aggravated by the operation. In his experience, conception results after operation in young women.

Dr. Howard A. Kelly remarked that he was glad to hear of the good results in Dr. Wilson's cases, as a year or more had elapsed. He thought cases of laceration of the cervix might be arranged in three classes:

1. When the cervix, although lacerated, remains soft and flaccid, there will be no consequent symptoms.

2. When cicatricial tissue is developed or ectropion is present, marked reflex symptoms will ensue.

3. When there has been natural repair, but with inclusion or formation of hard or scar tissue, there will also be marked reflex symptoms.

To this latter class belong those cases with hypertrophied glands and everted lips, of so-called erosion. The second and third classes must be relieved by rest and local treatment, and then operated upon to keep them well. Complete removal of the hard tissue and perfect union of the coaptated edges must be secured. Failure in either of these points will cause a return of the symptoms.

Dr. Baer remarked that the symptoms were not due to the laceration, but to its inflammatory consequences. To secure a good result the inflammatory condition must first be subdued, and then the operation of closing the laceration will be in order. It may take a long course of treatment to secure this necessary condition, but operation will probably fail to secure the desired relief without the preparatory treatment. I have found in some of these unsuccessful cases union of the external surface only, and in others fistulous tracts between the suture points. Cicatricial tissue seems to be sometimes formed after operation when union occurs by granulation. Simple laceration without ectropion is very rare, and he would advise repair of the laceration in all cases, to prevent future resultant inflammatory conditions. It is desirable to have union by first intention to avoid formation of cicatricial tissue and suture track fistules.

Dr. Wilson spoke of the choice of method in preparatory treatment. Local treatment once a week will often fail to have a good effect, when a week or ten days in bed, with douches of hot water and glycerole of tannin, on pledgets of cotton applied daily, will accomplish rapid relief of the local condition. Great care should be exercised in the removal of tissue, as complete closure of the cervical canal may happen. He has seen two such cases, which were detected at the next menstrual period after the operation. The passage of a spear-pointed probe gave vent to dark grumous material.

Dr. Howard H. Kelly exhibited a specimen of

Hæmatoma of the Ovary with Adherent Fallopian Tube.

This specimen is an example of a class of cases which stand peculiarly by themselves—cases of aggravated tubal and ovarian disease, on a small scale as compared with ovarian cyst, and yet in which there is enough change in the size and consistency in one or more of the structures of the appendages to afford most satisfactory ground for diagnostic precision under skilled bi-manual examination. These cases occupy a middle ground between the larger tumors, where disease is so palpable, and those haphazard attempts, the present reproach of gynecological surgery, in which the operation upon appendical structures is undertaken to relieve a *symptom*, and the diagnosis of pathological ovarian or tubal change is made after removal or not at all.

This is the right ovary of a patient 21 years of age. It is about the size and shape of a large Spanish chestnut. I was able to handle it freely by bi-manual examination, and determined exactly its size, shape, consistence, and relations, before operating. The indications for operative interference, after I had made my diagnosis, were greater than in the case of any large ovarian cyst I have ever seen, and the prospects and result of any form of palliation were futile. Almost the whole of this large ovary is filled with a blood-clot, soft and jelly-like in part, and in part firm, fibrous, and apparently intimately united to the ovarian stroma. This clot is surrounded by a shell of apparently normal ovarian tissue, throughout which are seen a number of follicles and old corpora lutea. A remarkable feature is the way in which the fimbriated extremity of the tube is spread out like a sucker over the surface of the ovary and glued fast by adhesions, so that the line of demarcation between tube and ovary is but faintly indicated. From the line of junction numerous vessels course in a radiating manner down over the ovary. The left ovary is below normal size, but contains many pea-sized black clots.

The second specimens which I now exhibit were removed this afternoon. The case is an example of the third class, in which the operator has nothing but a symptom to guide him. My patient, 35 years of age, suffered from an increasing menorrhagia for 14 years. Lately she has been bleeding half the time. She has had recourse to every possible plan of treatment, with but slight and temporary relief. The only thing I could do was to perform oöphorectomy and stop her menstruation. One ovary weighs 139 grains, the other 103 grains. A beautiful corpus luteum of menstruation, about two and a half weeks old, shows that the hemorrhages, which retained all along a menstrual periodicity, were in reality menstrual. The tubes are free from disease. In one ovary a globuiar pellucid cyst lies between the layers of the broad ligament in close proximity to the fimbriæ, the tubo-ovarian ligament being spread out over its surface.

Dr. Wilson called attention to the fact that in the first specimen the tube had been occluded by a torsion or twist upon itself.

Dr. Baer remarked that it would be interesting to know the results in Dr. Kelly's last case. In such a case there is of necessity a cause for the hemorrhage; there is no apparent diseased condition of ovary or tubes sufficient to account for it. Hemorrhages from the uterus are often associated with vegetations upon its lining surface, but these are not always present. He alluded to one case in which hemorrhage continued to be profuse after the removal of the tubes and ovaries, which had been very much diseased.

Dr. Price remarked that in this last instance the continued hemorrhage might be the result of body-habit, although the original cause might be removed.

Dr. Harris spoke of a case of fibroid tumor of the uterus with menorrhagia, in which removal of the tubes and ovaries gave complete relief.

Dr. Kelly had, eight months ago, removed both ovaries and tubes, and the menorrhagia still continues. In the case operated upon to-day the curette had been used, but no vegetations had been found. A strong tincture of iodine applied thoroughly to the inside of the uterus and vaginal packing would quickly stop the hemorrhage for the time, but it would soon recur. Operation was performed to relieve the symptom of hemorrhage by bringing on the menopause, and not because the ovaries were supposed to be diseased.

Dr. J. Price exhibited specimens from a case of

Pyosalpinx.

The tube was large as the finger and cheesy in consistence, and was easily broken, even by the bite of the hemostatic forceps. The patient was in a typhoid condition, with high evening temperature, emaciation, quick pulse, pain in locomotion. There certainly had been leakage of pus before, but two ounces escaped at the time of removal. Adhesions were numerous, but were cheesy and broke down readily. After the operation there was rapid subsidence of the pulse, and temperature with the other symptoms. Free washings of the abdominal cavity through a drainage-tube were practiced for a few days. There was a clear history of gonorrhœa. The other tube and ovary were not enlarged.

Dr. Beates remarked that in one case upon which he had operated, repeated attacks of peritonits had caused large deposits of flaky lymph in Douglas's cul-de-sac. These were nicely removed by sponging.

Dr. Baer raised the question of the gonorrhœal origin of the salpingitis in Dr. Price's case, which was unilateral, while gonorrhœa usually causes both tubes to become diseased.

Dr. Price stated that Dr. Tait's new book reported a gonorrhœal case of unilateral salpingitis. Comparing with the male analogue epididymitis, which is usually unilateral, would support the idea of such an origin. A free leakage of secretion from the tube, and absence of constriction, may prevent the accumulation of pus on one side.

Dr. Beates exhibited specimens from a case of

Diffused Sarcoma Uteri with Metastasis to Liver and Lungs.

The patient from whom the specimens were obtained was in excellent health until the development of this affection, æt. 59. Catamenia established during her sixteenth year without undue disturbance. She has had four children and no miscarriages or pelvic disease during her sexual life. There is no evidence of heredity toward myoplastic disease. Menopause at age of 48, without incident. About five years later a hemorrhage occurred, lasting a few days. It recurred with decided regularity, and the patient, believing it to be menstrual, did not have recourse to treatment until an intermenstrual sero-sanguinolent discharge appeared. Later this assumed a purulent type, and was accompanied by constant pain. The condition was now regarded carcinomatous. In June, '85, I found the patient emaciated, cachectic, and weak; digestion was impaired, and the stomach irritable. Local pain was intense, with nocturnal exacerbations. There was also incontinence of urine and its consequent intertrigo. The vagina was so occluded with numerous neoplasms, varying in size from mere nodules to the size of an olive, that an examination of the uterus was impracticable. Some of these were pedunculated. There was an offensive ichorous discharge; bleeding occurred upon the slightest touch. The history was one of progressive asthenia.

The autopsy by Dr. Formad disclosed the pulmonary apices and the inferior-posterior margins to be the seats of nodular masses. The surface of the left hepatic lobe was the seat of two deposits which simulated encephaloid carcinoma. The lymphatic glands were perfectly normal. The uterus was enlarged about one-fourth, and its attenuated walls were easily torn. Upon opening it, it was found to be almost entirely destroyed by ulcerative processes which were most marked near the fundus. The cavity of the pelvis

was occupied by the morbid mass and the vagina entirely destroyed. The bladder was not involved, but the urethra was sloughed through. Rectum free. The microscope showed a small-cell sarcoma. The pathological laws of which this is an illustration possess especial interest regarding treatment. It is now well known that neoplasms originating in areas that have developed from either the epi, meso, or hypo-blast possess certain specific life histories, and while all may closely resemble each other in their incipiency, differ widely not only in their course but ultimate results as they continue to exist. Thus epithelioma of epi-blastic structures is local and not subject to metastasis, while the hypo-blastic epitheliomata are preëminently metastatic. Meso-blastic neoplasms are of connective tissue type, and in large cell forms, local, while in small cell varieties metastatic. Epitheliomata undergo metastasis through the lymph channels; sarcomata, by means of the blood-vessels. Either of these diseases, when first becoming active, there is good reason to believe, is local, and before retrograde changes occur can, by total removal of the organ involved, be radically cured. As sarcoma, and especially its small-cell variety, is especially prone to metastasis, its early recognition is a matter of paramount import. In this case its early evidence was mistaken for carcinoma, and from a clinical standpoint alone such an error is unavoidable; but as the discharges contain portions of the neoplasm readily recognized by the microscope at a time when metastasis has not occurred, its diagnosis and treatment are a matter of simplicity. The later symptoms, absence of lymphatic involvement and comparatively slow course, enable one to know that he is palliating the sufferings of a sarcoma.

W. H. H. Githens, *Secretary.*

CHICAGO MEDICAL SOCIETY.

(*Continued from page* 431.)

Exhibition of Pathological Specimens from Battey's Operation, and Specimens of Ovarian Tumor with Twisted Pedicle,

By Dr. C. T. Parkes, who said:

"The specimens which I have to present to you on this plate are two ovaries and forty gall-stones. The two ovaries were removed from a lady who had suffered for over ten years from a great deal of trouble in the pelvis. They are noticeable in that the left one is very small and the right one very large. In this box are forty-three gall-stones, which I removed from a gall-bladder yesterday. In reference to the oöphorectomy, I desire to call attention to the knot used in securing the pedicle, and which has been rendered famous by Mr. Tait; he calls it the Staffordshire knot. Its use got me into trouble. It does not secure the pedicle by merely tying the knot. It must be drawn sufficiently tight to cut off circulation in the pedicle before the final knot is secured, otherwise the pedicle is very feebly constricted. I used it in this case in securing the left ovary, and passed on to the removal of the right ovary, during which operation I noticed that a good deal of bleeding was going on. Having removed the right ovary, I then looked for the point of hemorrhage, and found a spurting artery in the unsecured left pedicle. I was astonished, because I thought I had tied the knot very tightly. It is necessary that the constriction should be made by the string, and the circulation must be entirely cut off before any attempt at tying is made. The other specimen is a large tumor, the weight of which was estimated at twenty-three pounds. Eight days before the operation, the patient having been in a previous condition of apparent good health, was suddenly taken sick, temperature 102°, pulse very fast and feeble, abdomen tender from peritonitis, urine suppressed. I diagnosed a twisted pedicle, and advised immediate operation. The operation was done as soon as possible, and although she was in a very feeble condition at the time, the operation apparently made very little impression upon her. As soon as the abdominal incision was made a black tumor presented, and instead of the cyst portion being uppermost, as is almost invariably found, the solid portion was in front. When the trocar was pulled out, there was scarcely any hemorrhage from the opening made by it; usually there is considerable hemorrhage, especially when introduced into a solid tumor. When it was removed from the abdomen there was found to be a turn and a half in the pedicle. The temperature fell after the operation, and did not again come up to one hundred. On the seventh day all the stitches were removed, and the patient is practically well to-day. These tumors sometimes have pedicles twisted completely off, so that they are in a sloughing condition; in other cases the twisting goes on so slowly that the pedicle is finally destroyed entirely. Spencer Wells says that he has found tumors with no pedicles. The three points that seem to me to indicate this

diagnosis are the rapid occurrence of distention, the commencement of peritonitis, and the suppression of urine."

The President said in answer to a question that because a patient has symptoms of gall-stones, and the evidences are pretty positive of their presence, no one must imagine that thereby he is going to have an easy time of the operation. The case from which these gall-stones were removed was a very difficult one for operation. The patient was a woman of considerable adipose tissue on the surface of the body, and it was difficult to expose the gall-bladder at all. The liver, instead of being distended and projecting below the ribs, was contracted and high above them.

It was difficult to find the gall-bladder at first, and it was found to be about the size of a finger, elongated, and lying in its natural position and adherent to the liver. The fundus was contracted and hardened or thickened, so that the finger had to be passed well down along its surface before any evidence of the stones could be found at all; it was separated from its attachments to the under surface of the liver, and then by carrying a thread through its fundus it was lifted to the top part of the incision and the finger introduced into the cavity of the gall-bladder and the stones removed. Of these stones the largest was found in the gall-duct. It was forced from the gall-duct into the gall-bladder.

Dr. H. P. Merriman asked the President if any cause was known for the twisting of the pedicle in ovarian tumor.

The President said that he made very close inquiry on that point; the night previous to the occurrence of the trouble the patient felt something move in the abdomen from the left to the right side. She was lying in bed at the time. In reply to Dr. Strong, the President said he did not think that rupture of the cyst would not be followed by an increase in the size of the abdomen, nor by any change in the function of the kidney.

Dr. W. Franklin Coleman read a paper on

A Report of Three Cases of Ossification of the Choroid, and the Report of One Case of Ossification of the Lens, with Specimens.

In cases one, two, three, and four the eye had been lost five, twelve, fourteen, and thirty-four years respectively, before medical advice was sought on account of sympathetic trouble in the fellow eye. In cases one, two, and four the lost eye had occasionally been painful. In cases one, two, three, and four, sympathetic disease did not occur after the loss of the eye until five, twelve, eleven, and eighteen years respectively. The sympathetic disease excited in case one was serous kerato-iritis; case two, cyclitis; case three, irido-cyclitis and cataract; case four, optic neuritis and mild iritis. Dr. Coleman advised the immediate enucleation of a bony eye on the same ground that the enucleation of an eye lost from injury in the ciliary region would be advised. Neither the ossification nor the injury is in itself the immediate cause of the sympathetic disease, but either may be the indirect cause by exciting an irido-cyclitis.

Dr. R. Tilley said the term ossification of the lens might lead to a misunderstanding that there is actually ever an ossification of the lens. Becker, of Heidelberg, claims that ossification of the lens cannot and does not take place, and that there is no case of it on record. He says that in the case of a ruptured capsule a membrane may be developed from the ciliary region, and from the developing blood-vessels an ossification may take place in the region of the lens, but that it should not be called an ossification of the lens. He gives an interesting case showing how readily a mistake may be made and ossification supposed: A boy was struck in the eye with a hay-fork, and came under his care about ten hours after the accident. Forty-three hours after the accident the eye was enucleated, and he thought from a macroscopic examination that the lens was intact, but on microscopic examination what he supposed to be the lens was found to be an extravasation of blood, and the lens had escaped. He remarked that it is easy to see that an ossification might have occurred under these circumstances, and the same been taken for the lens.

Dr. Coleman said, in conclusion, that he was well aware that literally and truly the lens fibres do not become ossified, but wherever connective tissue exists ossification may occur, and connective tissue may occupy the site of the lens. Dr. Voorhies cites a case in his own practice of an ossific mass occupying the normal position of the lens, which an expert microscopist, upon examination, pronounced ossification of the lens. Dr. Knapp does not say he denies the possibility of such ossification.

CLINICAL SOCIETY OF MARYLAND.

Stated meeting held February 15, 1886.

Dr. Samuel Theobald read a paper entitled

Notes of a Series of Cataract Extractions by Von Grafe's Method.

Reference was made to the fact that the original operation of Grafe had undergone many slight modifications at the hands of different surgeons, especially as regards the character of the external incision, and the manner of making the iridectomy and of opening the lens capsule. In the cases reported, the operations had been done with a dilated pupil, the external incision had been made throughout in the sclero-corneal junction (a conjunctival flap being the exception rather than the rule), and the iridectomy (except in one instance) had been made by a single cut of the scissors, giving a comparatively small coloboma. In the character of the iridectomy the cases departed from the usual rule, and it was on this account they were thought of sufficient interest to be reported. Besides the optical and cosmetic advantages which it is generally admitted the small coloboma possesses, it was claimed that the excision of the iris in this manner is less apt to cause entanglement of the edges of the coloboma in the angles of the external incision than when a large iridectomy is made by several cuts of the scissors. Of the seventeen cases reported, fourteen were uncomplicated, and in all of these the operations were successful, V varying from $\frac{20}{xxx}$ to $\frac{15}{c}$.

Of the three remaining cases the cataracts were secondary to syphilitic irido-choroiditis in two, and to myopia in one. In one of the former V=$\frac{15}{cc}$ was obtained; in the other, the eye recovered well from the operation, but, owing to extensive pathological change in the deeper structures of the globe from former disease, no improvement in sight resulted.

In the case complicated by myopia (though the operation was a smooth one) the eye did badly from the first, and, suppurative panophthalmitis having supervened, it was enucleated.

Some of the operations were performed without anæsthesia, some with chloroform, and some with cocaine, the number in each category being about the same. Four of the patients were over 80 years of age. In all of them the operation was successful, and the healing process rapid and uninterrupted. In none of the cases was there loss of vitreous humor or other evidence of rupture of the hyaloid membrane.

DISCUSSION.

Dr. E. Mierhof listened to the paper with much interest. Especially was there one point that had impressed him, the fact that Dr. Theobald had used atropia in all of his cases before operating. Many writers recommend the use of eserine; they claim that it is much easier to make a clean iridectomy with a contracted than with a dilated pupil.

Dr. Theobald said his experience had been just the reverse.

Dr. Harlan gets a clean coloboma by trimming off all ragged edges at the extremity of the primary incision.

Dr. Mierhof gets the ragged edges back into the eye by stroking lightly over the corneal wound.

Dr. Hiram Wood says it is Dr. Chisolm's practice to pull them into position by inducing contractions of the pupil by the use of eserine.

Dr. Harlan asked Dr. Theobald if drops were used in the eye after each operation.

Dr. Theobald said if there is no reason for doing otherwise, he does not remove the bandage for three days, then he instills atropia drops into the eye. He thinks efforts to release the shreds of iris from the corneal wound by stroking, have a tendency to bruise. He don't approve of pushing them into position by small instruments. He avoids ragged edges by making one single clean cut into the iris.

Dr. Frank Donaldson, Jr., then read a paper on

Pneumatic Differentiation.*

Dr. H. Clinton McSherry thought the greatest therapeutic value of the Pneumatic Cabinet, as pointed out by Dr. Donaldson, was in the application of a medicated spray directly to the diseased tissues. He does not consider it an apparatus that should be placed in the hands of every one, as unless used with extreme care it is capable of doing extreme mischief.

He would like to hear from a series of cases treated by this method alone. Most, if not all, of those referred to by Dr. Donaldson, were under other treatment at the same time.

Dr. I. E. Atkinson read a paper on

Scarlatinal Nephritis.

Dr. Wm. H. Welsch thought Dr. Atkinson's paper contained many points of interest, especially the conditions found in these kidneys, and agrees with Dr. Atkinson in looking upon this form of renal affection as being of a specific nature. It is the only form of nephritis that has been thoroughly investigated. He considers the form of the affection to be a glomerulo-nephritis.

*See Maryland Medical Journal, February 18, 1886.

The tufts are swollen and contain cell infiltration due to proliferation of the epithelium, being Bowman's capsule and that covering the tuft. These cells accumulate in the space between the tuft and the capsule, and give rise to a *crescent-shaped* accumulation, that seems to be typical of this form of nephritis. Again there is a small cell infiltration around the afferent arterioles of the glomeruli which cause a narrowing of the lumen, hence a lessening of the amount of blood going to the tuft and a consequent decrease in the amount of urine passed in this disease. He finds these conditions very constantly occurring.

The micrococci found in the kidney, he takes it, are the same as those found in the other acute infectious diseases that give rise to suppurative nephritis. They are in all probability the common organism of pus.

He thinks that in dropsies without nephritis the trouble resides more in the vessel walls than in any derangement with the kidneys.

Dr. W. Winsey reported a

Case in which the Placenta was Adherent in Successive Labors.

Dr. W. H. Norris has seen a number of cases of adherent placenta, and in all of them was he able to trace the cause to some traumatism.

Dr. Wm. A. Moale showed a cast of a knee-joint which illustrated the position taken by the limb when fracture of the internal condyle of the femur takes place, as was the case in the patient from whom the cast was taken. He reported the case because of its rarity. Agnew knew of but 15 cases ever reported.

Periscope.

Antipyretic Treatment.

Dr. M. A. Veeder, of Lyons, N. Y., sends the following to the *Med. Record*:

The use of certain drugs for the purpose of reducing the temperature is very liable to become a mere matter of routine. The ease and certainty with which fever is detected by means of the clinical thermometer, leads to the habitual use of this instrument, with the effect of concentrating the attention upon changes of temperature to the neglect of other symptoms. The obvious consequence of this tendency is an undue reliance upon fever mixtures of one sort or another. In regions where this therapeutic fashion holds full sway, but few patients escape being dosed with quinine, aconite, the salicylates, antipyrin, or some other wonderful antiphlogistic. Unquestionably such drugs have their proper uses, but they should not, therefore, be employed hap-hazard in every case of elevation of temperature. In fact, their routine use does harm by preventing the adoption of measures having real efficiency. In typhoid fever, for instance, it should not be forgotten that healing the ulcerated bowel moderates the fever most effectually. It has been the fortune of the writer to see an extremely severe case of typhoid fever recover without the use of any of the ordinary antipyretics, the high temperature as well as the other symptoms yielding under treatment directed almost entirely to remedying the condition of the bowel. Thorough digestion of the nourishment given, and the use of turpentine, bismuth, and opium, in accordance with their well-known effects, were the means employed. The principle involved in this method of treatment is to attend first to the primary lesions of the disease rather than to its symptoms. Fever will cease if the disorder upon which it depends has been remedied. Thus fever dependent upon indigestion can be relieved, not by aconite or quinine, but by clearing out the bowels. A stimulating expectorant like carbonate of ammonia, liquefying and removing foul accumulations, will often have a more decided effect upon the temperature than any of the regular antipyretics. In case of sore throat with bad breath, chlorine water, attacking the disorder in its very seat, may relieve all the symptoms, feverishness included. Certain malarial fevers may have their power broken by methods that do not involve the swallowing of any drugs whatever; only clean out the filthy cellar of the nasty drain, or trap the sewer on the premises, and fever takes its departure like a whipped cur. Improper splints or bandages may cause feverishness after surgical operations. In such cases, instead of dosing with quinine, smooth out the wrinkles, and put the wounded part in as comfortable a condition as possible, and the

patient becomes as serene as a morning in May. Puerperal fever not unfrequently disappears, as if by magic, when the uterus has simply been freed from malodorous materials and thoroughly disinfected. In dealing with wounds and sores generally, absolute cleanliness is the best antipyretic. In fact, the whole subject of antiseptic treatment, which looms up so largely in these days, may properly be regarded as but a phase of the subject of antipyretic treatment. As a result of modern researches into the nature of disease-germs and wound-infection, it is evident that the physicians are fast becoming better able to deal with the causes as well as the symptoms of disease. It is safe to say that the time is approaching when Medicus will no longer thrust a fever thermometer beneath his hapless patient's tongue, and then with an air of vast scientific superiority prescribe a fever mixture hap-hazard.

The Treatment of Chronic Ulcers.

Dr. William Stuart Low thus writes in the *Brit. Med. Jour.*, February 20th: So much doubt has been expressed, diffidence entertained, and practitioners so frequently stigmatized as rash or timorous, according as they attempt or not to heal chronic ulcers, that a clearer understanding of their treatment and its effects is much to be desired. That there is no danger in the perfect cure of long-standing and much discharging ulcerated surfaces, I maintain; and I cite the following case in evidence.

R. S., male, aged 48, had suffered for twelve years from a very extensive ulceration of the right leg. During this time, a great variety of treatment had been tried—rest, bandaging, baths, and numerous internal medicines. I found the case one of extensive serpiginous ulcer, almost one mass of broken surface on each side of the knee, back of the calf, and popliteal surface, and even extending to the posterior surface of the thigh, at some points granulating, and at others sloughing, bleeding on the slightest injury. The surfaces were deep, and the edges raised and hard, with much surrounding induration. The discharge was very offensive, and this especially so from the grumous pus expressed from numerous sinuous channels ramifying about the limb.

My patient being in easy circumstances, I had full liberty as regards any expense I might incur, and determined to make one last endeavor. I attacked the whole surface by means of a thorough ablution with a lotion of the solution of bichloride of mercury, of the strength of one drachm to eight ounces of water; this was practised daily, syringing most carefully every part of the wound, and with speedy benefit. The discharge rapidly lessened, the fœtor diminished, and the sloughing ceased. New granulations sprang up all over, although not without considerable loss of blood from recurrent attacks of hæmorrhage as the dead tissues separated and the feeble granulations gave way. The dressing consisted simply of lint wrung out in the bichloride lotion of similar strength, and applied directly to the wounds.

The second feature in the treatment that I am anxious to emphasize is the utility of iodoform as a local anæsthetic. This was very marked, relieving the pain sorely complained of in many irritable spots, contributing greatly to the comfort of the patient, and facilitating exceedingly the daily dressing. The iodoform was used freely in the form of a fine powder, dusted upon the painful spots. It proved valuable also in quickly inducing healthy action in the indolent portions of the ulcer, and, as an antiseptic and deodorant, maintained a perfect sweetness of the discharges.

I observed, in the local employment of powdered iodoform, however, that its use must not be persisted in too long, or the healthy action obtained is soon undone, the granulations breaking down under its continued action, and much bloody discharge staining the dressings; indeed, a blood-stained dressing, where iodoform had been applied, became the indication to cease its employment there. While preparing the wound for cicatrization, by stimulating the surface, it rather retarded the growth of the cuticle, and simple dressing with bichloride lotion proved more efficacious. Lastly, its application to an inflamed surface should be studiously avoided, as it tends greatly to aggravate it.

The beneficial effect of these remedies is more remarkable, when I state that this patient rested his leg but little. Rest was a part of my prescription that he stoutly resisted, daily walking short distances, driving out, and going up stairs. It was here that the third important point in the treatment proved invaluable; the use of resilient pressure, in the form of a Martin's elastic bandage; this was daily applied over the other dressings, from toes to thigh.

During the interval of six weeks since commencing these measures, the progress has been uninterrupted, and the cure is now complete; and I trust such encouraging results

will animate many to essay the successful therapeutics of chronic ulceration.

Epilepsy Cured by Removal of Nasal Polypi.

The following case, which Fincke reports in the *Deutsche Med. Woch.*, January, 1885, is interesting, as contrasting with the obscurity which usually characterizes the etiology of epilepsy. N., a powerfully-built man, apparently in good health, was returning from a visit to some friends, when he suddenly fell to the ground with a loud cry. He was raised, and carried to the house of a bystander, where he soon regained consciousness. He recollected nothing of the attack, and felt no pain, though he had by the fall on the curbstone sustained extensive contused wounds of the scalp. On the following day his intellect was clearer; still, there was no recollection of the fit. On the third day after the attack the temperature rose to 38.5° C., the scalp commenced to swell, the face became œdematous, and slight delirium set in. Suppuration followed, and patient continued in a critical condition for a month. Ten weeks after the attack he was able to read and understand as before the fit. The wounds of the head slowly healed one after the other. All seemed going on well, when a hurried message was brought to the effect that N. had had another attack, and lay dying. He was in bed, his face cyanotic, eyes closed, and breathing with difficulty. Suddenly the eyes opened, and with a cry the patient became violently convulsed, and frothed at the mouth. The attack lasted from six to eight minutes, then a pause of ten minutes, when another fit occurred, then an intermission, and so on for six or eight hours, an intermission of about fifteen minutes occurring between each attack. Four weeks elapsed before N. recovered from the effects of this group of attacks, during which time he took bromide of potassium, fifteen grains thrice daily. Shortly after this, patient complained of what he thought was a cold in the head, together with difficulty in swallowing. On examination a polypus was seen, blocking up the right nasal cavity. With the hope that this might be the cause of the epileptic seizures, a mass of mucous polypi was removed, which had completely obstructed the nasal passage. From the time of the operation, in order to render the result more decisive, the bromide of potassium was discontinued. Two years have now elapsed since the operation, and N. has not experienced the slightest indication of an epileptic attack. Dr. Fincke, in conclusion, remarks that there was no spot of the nasal mucous membrane specially irritable, and no trace of swelling of the erectile tissue of the turbinated bodies. The pharynx was healthy. He therefore feels justified in believing that in the above case the stoppage of the nose by the mucous polypi interfered with breathing, more especially during sleep, and that thus the return of the blood from the brain was impeded, causing an accumulation of carbonic acid, and so producing the cerebral symptoms noticed before the last attacks, and culminating in the epileptic fits.

The Administration of Chloroform.

Dr. John C. Kerr thus writes to the *Southern California Practitioner:*

Medical men are well aware (some painfully so) of the fact that the administration of chloroform is a dangerous procedure, excepting, perhaps, in obstetrical cases, and are very reluctant in giving it in general surgical practice, because of its paralyzing action upon the heart. Probably every medical student in America has been warned, emphatically, during his college course, about the danger of administering chloroform; indeed, so great stress is put upon it that many enter practice with the determination never to try it, and I have met with physicians who have been in active practice for a number of years, and who have told me they had never yet dared to give chloroform. I, myself, started out with the same determination, but I soon found that time was too precious and the effects of ether too disgusting to hold me to the old resolution; therefore, I began anew the reading of therapeutics and physiology, with the view of finding some drug which might counteract the effects of chloroform or be antagonistic to it. I began to experiment practically, by trying spirits of ammonia aromat., brandy, and all the cardiac stimulants; but in many cases (the usual percentage) the lips and nose were as blue as though I had used no stimulant, and the pulse as small and weak. I investigated thoroughly the physiological action of nearly all the prominent drugs in the materia medica and studied their action upon the different structures, especially the brain and spinal cord, and the result was a choice of belladonna.

Now, this drug is physiologically antagonistic to chloroform, it paralyzes the termination of the pneumogastric nerve in both heart and lungs—as proven by Drs. Ringer, H. C. Wood and others—and stimulates the sym-

pathetic, which is exactly the reverse action of chloroform. I therefore concluded to try the hypodermic injection of one-twentieth of a gr. of atropia at the next opportunity and watch the result. The subject was a lady, having already a weak heart and in a run down condition from the effects of malignant disease of the breast (the skin being considerably involved). I gave her the above dose of atropia hypodermically, and then began the administration of the anæsthetic. She took it without a murmur; there was no trouble in breathing, no blue lips or nose, and the heart's beat was regular and even stronger than usual, and I completed the operation without a single bad symptom.

This was the first encouragement, and I concluded to try it in every case where an anæsthetic was needed, which I did, with similar results.

Care must be exercised, however, against giving too large doses of belladonna, lest the sympathetic nerve force become exhausted by over-stimulation.

The Causes and Treatment of Quinsy.

Dr. F. P. Atkinson thus writes in *The Practitioner:*

Having been in years past a frequent sufferer from quinsy, I have taken special interest in determining its cause or causes and the best methods of treatment, and I believe I can, after twenty years of experience, speak with confidence as to the correctness of my present views. First of all, then, I would say, it is essentially a disease of debility, and is more or less associated with *adolescence* and a strumous habit. The exciting causes are sexual excesses, bodily fatigue, irregularity of meals, long-continued fasts—or, in other words, excessive nervous or muscular exhaustion. Cold and rheumatism play little or no part in its production—nervous and muscular exhaustion, as I have said, are the immediate causes of quinsy, and both these make the person also liable to take a chill and so rheumatic fever. However, I have rarely, if ever, in the whole course of my experience, seen these two coëxisting in the same person. Again, it cannot be the result of cold acting directly on the throat, because laryngitis would then be a much more frequent accompaniment than it now is, and a second attack rarely follows till after the lapse of some months, no matter what the amount of exposure. The *treatment* I have to advise can scarcely be termed otherwise than a specific one, since I can with perfect truth affirm that very few, if any, of the cases have gone on to suppuration which have come to me at a early period.

The effervescing citrates will be found useful in allaying not only this, but all other kinds of glandular inflammations, and I order twenty grains of bicarbonate of potassium to be taken with fifteen grains of citric acid every four hours, in a state of effervescence. Guaiacum, which has long been known to be beneficial in throat cases, is best given in the form of lozenges made up with black-currant jam, in accordance with the directions of the pharmacopœia of the Throat Hospital, Golden Square. One of these lozenges should be sucked frequently. Iodine, when applied locally in cases of glandular inflammation, is known either to reduce the enlargement or to hasten suppuration, according to the stage in which it exists; and a gargle, containing from twenty to twenty-five minims of the tincture to the ounce of water, will be found particularly useful. This may be used by taking a little in the mouth, and shaking the head from side to side. Port-wine is an essential part of the treatment, and it is necessary for the patient to take from four to six ounces in the course of the day, besides plenty of beef-tea and milk. By this method resolution is almost always brought about, and the patients are, with scarcely a single exception, able to resume their usual duties about the fourth day. The usual duration under the old methods of treatment was almost always from nine to ten days. I would particularly urge upon those who are willing to give the above-mentioned method of treatment a trial, not to be discouraged if the patients complain of feeling no better, or even worse, for the first two days, but to persist with it all the same, and they will be certain to meet with the success they and their patients desire. Though the bowels are almost always confined, it is not advisable to administer aperients, since as soon as recovery takes place they are moved as regularly as possible, without any extraneous assistance. When suppuration has commenced in the tonsils (which may be looked for about the sixth day, and made out by great throbbing in the ear on the affected side), it is best to omit the effervescing citrates and guaiacum lozenges, and depend upon the iodine gargle, together with the port-wine and beef-tea. Suppuration is by this means hastened and suffering curtailed. In conclusion, I would ask those who put this method of treatment on trial to keep a record of their cases, and after a time make a report both of the successful and unsuccessful ones, so that we may

arrive at really truthful conclusions concerning this disease.

Intussusception of the Upper Part of the Jejunum, of Twenty-one Months' Standing.

Before the Clinical Society of London, Dr. Goodhart read notes of this case. Its clinical interest depended upon its long duration, and upon the resemblance of the abdominal tumors during life to a floating kidney. The case occurred in the practice of Mr. Sandford Arnott, of Brixton. The patient, a girl, æt. 19, had been first seen a year and three-quarters before her death, and was then suffering periodical attacks of vomiting and abdominal pain, with progressive wasting. A knotty, irregular tumor was felt in the lower part of the abdomen above the uterus. She then attended the out-patient department at King's College for eight months, and subsequently at University College, with obstinate constipation, fæcal tumors, and what was thought to be a floating kidney. She was relieved by enemata of sulphate of magnesia, but notwithstanding her attacks recurred, and in these she was frequently seen by Mr. Arnott. The abdominal tumor never disappeared, but latterly it altered its position, and came to correspond with the situation of the left kidney. It varied in size and shape, some days being decidedly kidney-shaped, and generally it had a curve in its length, the concavity being towards the umbilicus. She was seen by Dr. Goodhart in her last attack because the vomiting had been more severe and continuous than before. She was then pale and very thin, although not giving the appearance of any extreme emaciation; her mother described her as hardly ever free from sickness for more than a week, the actual attack lasting generally 24 to 36 hours. Lately she had been sick almost daily. The abdomen being exposed, the existence of a dilated stomach was at once apparent: it occupied the upper half of the abdomen, and its muscular contractions were plainly visible; but below this, in the left inferior quarter of the abdomen, was a second tumor, running from the flank obliquely downwards towards the pubes. This was the mass that had been felt throughout the progress of the case. It was an elongated tumor that underwent slow rhythmic alterations, becoming alternately hard and soft, and was obviously some part of the intestine in labor. Vaginal and rectal examination gave no additional information. However, it was clear that there was some intestinal obstruction, although there was no sufficient material for determining its exact nature. She had never passed any blood, the evacuations being always of a light brown color, and although she suffered from constipation it was never such as to resist the action of an aperient. It was arranged that she should be admitted to Guy's Hospital, but before this was accomplished she died, apparently from the exhaustion of the continued vomiting. Mr. Arnott and I made an inspection. The dilated stomach occupied the greater part of the abdomen; below, and to its left, in the inguinal region, were two or three coils of small intestine, small, but prominent, as if something pushed them up from behind, and on turning them aside a large intussusception was seen; it ran from near the spine into the pelvis, and looked more like rectum in thickness and size, but it proved to be small intestine, the neck of the intussusception being at the commencement of the jejunum. It was about eighteen inches in length, and when further examined was found to be associated with, and no doubt caused by, the existence of large polypoid masses of growth which sprang from the mucous membrane of the small intestine in several parts.

Aneurism Occurring in a Stump.

Before the Clinical Society of London, Mr. Symonds read a paper on this case. A man, æt. 46, sustained a compound fracture of both bones of the leg in the site of an old syphilitic ulcer, on the floor of which the tibia was exposed; and was admitted into Guy's Hospital, August 7, 1883. Gritti's amputation was performed under full antiseptic precautions. The man was cachectic, and had lost a good deal of blood. Suppuration, with a foul discharge, occurred, and, later, two abscesses were opened on the outer side, and one on the inner side of the stump. Healing took place very slowly, and when discharged, nine weeks after the operation, the stump was somewhat swollen and hard, especially on the inner side. Five days later he returned with blood oozing from a pen-like opening in the original cicatrix; and two days later, when admitted, the bleeding was severe, and a large pulsating swelling was observed on the inner side. The skin over it was red and œdematous. There was thought to be an abscess communicating with the femoral artery. Before laying open the swelling, the superficial femoral was ligatured, the whole thigh being œdematous. When cut into, blood alone escaped. The incision was enlarged, the clots turned out,

when alarming hemorrhage occurred from the femoral. This was found to come from a small aneurism, which had ruptured. This was laid open, and the vessel tied above and below. The artery was isolated by passing a catheter into it. The man ultimately recovered, though slowly, and had a sound and useful stump. In his remarks, Mr. Symonds said the aneurism had formed on the vessel, two inches above the amputation site, and existed previous to the man's first discharge, and had ruptured soon afterwards. He referred to the rarity of the case, and to the general belief that aneurism does not follow ligature of a healthy vessel from pressure, nor embolism of an artery unless the embolus be in a state of active change and sets up a similar inflammatory and softening process in the wall of the vessel itself, which then yields to the ordinary blood-pressure. Admitting these facts, Mr. Symonds thought that a condition similar to that found in embolism must be looked for to explain the present case. It was suggested that the explanation of the cause of the aneurism lay in the inflammatory state of the stump, and Mr. Symonds thought it best explained by supposing the vessel to have been involved in the acute inflammatory process which ended in other parts in the formation of pus, but in the vessel in softening only. He supposed that a periostitis existed, reducing the vessel wall to an embryonic state, just as was seen occurring in the floor of ulcers, and in inflamed connective tissue. The localization was explained by supposing that at the point affected the vessel formed part of the wall of an abscess or sinus. In support of this suggestion, the condition of the vessels in the walls of phthisical cavities, from which hemorrhage occurred, was cited. Here, either an aperture in the wall of the vessel was found, or an aneurism. The latter change, he believed, was not uncommon in phthisis, and Mr. Symonds suggested that aneurismal dilatation will be found to precede secondary hemorrhage in stumps more frequently than is now supposed.

The Causation of Pleurisy.

The *Boston M. and S. Jour.* says that Germain Sée in his most recent work on "Simple Diseases of the Lungs," arranges the numerous varieties of pleurisy into two great categories: (1) Pleurisies by propagation; (2) Pleurisies by infection. The group of pleurisies from cold (pleurisy *à frigore*, or idiopathic pleurisy) he divides up, apportioning a part to the first category and a part to the second. He denies that cold is, properly speaking, a *cause* of pleurisy, aud thinks that it can only favor the development of pleural inflammation by permitting the real cause to act more rapidly or more efficaciously.

Pleurisies by propagation take their origin from lesions of the thoracic walls, thoracic organs, or neighboring viscera. Among the parietal lesions are osteo-periostitis, costal caries, parietal phlegmon, and even cancer of the mamma. Other propagating lesions are broncho-pulmonary inflammations (pleurisy is a constant accompaniment of acute fibrinous pneumonia); pericarditis (especially when the latter is due to rheumatism); hepatic affections, such as acute hepatitis, hydatid cysts of the convex surface of the liver, atrophic or hypertrophic cirrhosis: here the pleurisy is generally right-sided and the propagation takes place by the lymphatics.

Among the pleurisies by infection, first in the order of importance and frequency is tuberculous pleurisy. Tuberculosis is a very common etiological condition of pleurisy, being the determining cause in three-fourths of the cases, according to Professor Sée. Fiedler's statistics in this regard are very instructive; out of 112 cases of pleurisy treated by thoracentesis, only 21 recovered —of the 91 other patients, 25 died of phthisis at the hospital or at their homes, 66 got well of their pleurisy but were found to be victims of confirmed phthisis or other tubercular affections. Pleurisy has also been known to supervene in the course of diseases unquestionably rheumatic, and hence in these cases might properly be ascribed to the rheumatic virus, which Sée considers of an infectious (microbiotic) nature. Lastly, all the infectious diseases properly so called —scarlet fever, measles, surgical or puerperal pyæmia, typhoid fever, small-pox, blenorrhagia, etc., may be attended with pleurisy as a part of their manifestations.

As for the pleurisy which so often accompanies chronic Bright's disease, two explanations may be given. Either the pleurisy is the result of the pulmonary lesions which are so frequently a concomitant with Bright's disease, or else it develops in consequence of the general hæmic alterations of that disease, which provoke pleurisy as they do inflammations of other serous membranes. If the latter explanation be the correct one, the pleural inflammation would belong to Sée's second category.

The views of the French professor will not probably be generally accepted, as there doubtless do occur cases of simple acute pleurisy which are more easily referred for their origin to exposure to cold than to any

other cause. Yet it is quite possible that such cases are fewer than one would suppose, and that pleurisy in this respect resembles peritonitis, which is rarely idiopathic, and rarely *à frigore*.

A Case of Co-existence of Scarlet Fever and Measles.

Dr. Francis F. Brown thus writes in the Boston *Med. and Surg. Jour.*: Gertrude F., aged thirteen, was taken Thursday evening, January 28, with an attack of scarlatina anginosa. It was ushered in with vomiting and delirium. The vomiting persisted three or four days, but after the first, seemed to be kept up by the irritation of the fauces produced by the swelling of the throat. The eruption was out on Saturday, the 30th. The attack was severe, the throat badly swollen, the breath at first foul; pulse, 125 to 130; temperature, 103° to 103.9° in the axilla up to the following Thursday.

On Monday, February 1st, there was some cough, and for the two days following, and her face had a peculiar spotty look; this and the next were her sickest days. On Tuesday, her face was covered, mingled with the scarlet fever rash, with an unmistakable eruption of measles; none were seen on the body. Just ten days previously, her younger brother first broke out with the measles. The respiration was hurried also, somewhat, but less so the next day. Wednesday, the eruption of measles had extended over her body and limbs, mingled with the scarlet rash, while on her face neither could be distinguished; but the skin of it, with the exception of here and there a whitish spot, was of a uniform dark-red color, and elevated, giving it a peculiar look, as if covered with a red mask.

On Thursday, February 4th, the fever had abated, and from this time she convalesced. The general redness and elevated appearance of the face was gone, leaving the eruption of measles again distinct, and it could be faintly seen here up to the 6th and 7th. Both eruptions were fading on the body, and after that day none of the appearances of measles were seen there, while the redness from the scarlet fever remained a little longer.

This case is reported on account of its infrequency. The case of varicella occurring simultaneously with scarlatina, reported by Dr. Ayer in the *Journal*, February 4th, 1886, shows that such distinguished authorities as John Hunter and Hebra were too sweeping in their assertions that the eruptions of two exanthema never co-exist. The appearances in this patient were closely watched and noted at the time, and I do not think I could be mistaken. There has certainly been no lack of opportunity in this vicinity, of studying the characteristic features of measles the present winter.

A little reflection will show that the variety of this combination of the two diseases does not by any means prove their incompatibility. The chances that any patient will be so exposed as to bring on both at the same time are extremely small, and this may in part, at least, account for its infrequent occurrence. A few cases of scarlet fever known to have been fully exposed to measles from ten to fourteen days before, and failing to get it, would tend more to show their incompatibility than the bare fact of the infrequency of their simultaneous appearance.

Reviews and Book Notices.

BOOK NOTICES.

A System of Practical Medicine by American authors. Edited by Wm. Pepper, M. D., LL. D., etc. Vol. iv. Philadelphia: Lea Brothers & Co.

No testimony to the value of this work could be given higher than the general satisfaction which is expressed by those who have received the volumes already issued. We are in a position to say that this is widespread, and, indeed, we have not heard yet expressed an unfavorable criticism of the work as a whole.

The present volume contains monographs on the diseases of the genito-urinary and cutaneous systems, and on medical ophthalmology and otology. The contributors are twenty-one in number, all well known in the special departments to which they have been requested to write. More than two-thirds of the pages devoted to diseases of the genito-urinary system are occupied with diseases of women, ovarian, uterine and vaginal. In this portion we have a series of excellent treatises by such authorities as Byford, Goodell, Jaggard, Skene, Baer, Thomas, and others. Diseases of the skin are discussed by Duhring, medical ophthalmology by Norris, and medical otology by Strawbridge. The authors on diseases of the male urinary tract are Edes, Delafield, Tyson, Cross, and Keyes. Such names as these are guarantee enough of the character of the work done.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

COFFEE AS A DISINFECTANT.

Years ago some studious German made the observation, the correctness of which he endeavored and to a great extent also succeeded to establish by statistical data, that coffee, if taken early in the morning on the empty stomach, acted as a preventive against infectious and mainly acute epidemic diseases. He quoted a great number of cases where individuals accustomed to drink a cup of hot coffee for breakfast, had either escaped an epidemic of typhoid then ravaging the part of Germany in which the observer lived, or if attacked by the disease, contracted it in a much milder form; while all those who died from the disease had not been in the habit of taking coffee in the morning. This was a good number of years ago, at a time when in many parts of Germany coffee was still either an unknown or so costly a beverage as to be looked upon as a luxury that only the rich could enjoy. We have forgotten the name of the physician, but remember that the medical profession did not take kindly to the idea of coffee being a disinfectant, or as they then said, an anti-zymotic, and those who could not deny the correctness of the observation itself, ascribed the apparent immunity to other causes, many to the hot water with which the coffee was prepared.

That the physician, however, has not been so wrong, has been but recently proved. During the last meeting of the Prussian army surgeons in Berlin, Medical Director Oppler reported that after extensive investigations, which he related in detail, he had discovered that we possess in coffee an antiseptic remedy of no mean value, but one which could well serve for the purposes of a first dressing of a wound received in a battle. If employed at once it totally prevented suppuration, but if used after pus has already accumulated in the wound, it leads to the formation of a scab, beneath which the wound heals with complete asepsis. The coffee should be employed in the form of powder, and as it might entail the loss of valuable time to have to grind first the roasted coffee bean, which in Prussia every soldier is bound to carry about him, O. recommends the use of coffee-tablets, which have been recently discovered by a Hamburg firm, and which answer their purpose admirably well, as it is only necessary to rub these tablets a little, when they at once assume a powder form.

Dr. Oppler presented two cases at the meeting, where an injury of the head, accompanied by a great deal of laceration of the

soft tissues, had been treated with powdered coffee alone, and when the wounds had healed as well and as quickly as under strict aseptic treatment. He applies the coffee in a similar manner as gypsum is used in bandaging, viz.: he takes a gauze-bandage and partly spreads the powdered coffee over it, partly presses it into the bandage, with which the wound is to be covered.

He also made some experiments with urine, blood, glue and meat, which under the aseptic influence of coffee he managed to preserve for a long time in an unaltered condition. A colleague of his employed a salve, to which coffee had been added, in two cases of eczema, connected with a great deal of moisture, and in both cases a rapid cure resulted.

The aseptic action of coffee seems to be less due to the caffein than to the aromatic constituents, which are set free when coffee is roasted. Considering the cheapness of coffee and its easy procurement, Oppler's discovery may yet prove of great value.

CATARRHAL ICTERUS TREATED BY THE "KRULL'S INJECTION."

The tedious improvement in this purely functional affection, following the use of the accepted treatments, makes us turn with interest to any simple method which promises more rapid and radical results. Such an one is that described by Krull, in the *Berliner Klinische Wochenschrift* for 1877, No. 12; "an injection, per anum, of *cold water*, is made by means of an irrigator once in each 24 hours." He proved the value of his plan on eleven separate cases, and now Löwenthal comes forward, in the March 1st, 1866, issue of the same journal, with a report of its action in forty-one cases—there being but one (partial) failure. One litre of fluid sufficed for a child, and from one to two litres for an adult. Four days generally sufficed for treatment; six were rarely necessary. As for exact temperature, from 59° on the first day it was raised to 72.5° on the fourth. A passage invariably followed the first injection; sometimes there was even diarrhœa, which latter always ceased after the second lavement of rather warmer water. The first operation always consisted of gray, colorless or clay-colored masses; after the third, almost always yellow; after the fourth, the usual normal brown appearance. With the first enema there followed a cessation of abdominal pain, of pressure upon the stomach and liver, and of headache. Only after the second or third day was there improvement in appetite, relief from the general aching usually felt, and the lassitude present. Then, too, although the jaundice began to improve after the first day, some yet remained even after the stools had regained their normal color; the same may be said of the disappearance of bile from the urine. "Gelbsehen," or seeing all objects in a yellow color, was noticed in two of the cases, and disappeared after the first and second injection.

Pruritus of the skin, occurring in seven patients, was cured after the second and fourth enema.

Dr. Löwenthal cites five of the more interesting of the cases at length, and adds sundry remarks upon the probable cause of the affection, all of which goes to explain his text.

A MARTYR OF SCIENCE.

From our exchanges we learn that Carrion, one of the most eminent physicians of Lima, for the purpose of determining the real pathogenic cause of the verruga peruana, a virulent fever of low type, then epidemic in Lima, inoculated himself with the blood of a child suffering from the disease. Exactly twenty-two hours later the first symptoms characteristic of verruga broke out in him, and on the seventh day he died, while the child completely recovered. The fever is also known by the names of fiebre de la oroga and of fiebre anemigante. It greatly resembles the low fever endemic in the marshy districts of Central America, especially in Panama and in the neighborhood of the Amazon river; but it has besides one very peculiar symptom, viz., the rapidly-increasing anæmia, so that strong and robust persons, if the victims of the fever, seem to have no blood left on the second or third day.

Carrion's name adds one more to the many who have fallen victims to science. The world is apt to speak of heroes only on the battle-field, or when they died, faithful to their convictions, at the stake; but he who dies while trying, by sacrificing his own life, to relieve humanity from suffering, surely is a greater hero than any other, for there is no egotistical thought whatever connected with his martyrdom. The medical profession of the coming ages will reverently preserve the memory of Carrion. Requiescat in pace!

—The Prince of Oldenburg, commander of the Russian Imperial Guards, intends to found an establishment at St. Petersburg for the treatment of hydrophobia by inoculation, and preliminary experiments are now being made.

Notes and Comments.

Perfection of Ophthalmic Surgery.

Dr. Galezowsky (*Deutsch. Med. Zeit.*, January 4, 1886), has discovered the last step necessary to make the operation for cataract really complete, and if the observations of others confirm his statements, his discovery can really be called a valuable and important one. The cause why in many cases where an incision had to be made into the eyeball, the otherwise successful operation was not quite a success, or the result not quite as expected, has to be ascribed to the fact, that surgeons could not prevent the wound in the bulbus from coming in contact with the conjunctiva palpebrarum and the conjunctival secretion. Naturally, of the occlusion of the wound by a bandage, as usually practiced in surgery, nobody could think in case of the eyeball. Galezowsky conceived the idea to employ gelatine for this purpose, and after many unsuccessful trials he has at last succeeded in making a so-called gelatine-taffet, which, while well borne by the eye, tightly adheres to the wound, is slowly dissolved and gradually absorbed. This taffet consists of very smooth and thin gelatine-plates, which are now manufactured by the apothecary M. Wurtz, in Paris. They contain some corrosive sublimate and some cocaine, which are both set free during the slow melting of the tablets, and exert, therefore, their special antiseptic and anæsthetic influence. Besides, one side of the tablet is covered with glue, which causes it to adhere tightly to the eye, and the glue is so prepared that, while containing nothing whatever irritating to the eyeball, it is dissolved much slower than the gelatine, and remains, therefore, to the last, and always a sufficiently long period to prevent any contact between the wound and the palpebral conjunctiva until after perfect closure of the incision.

According to Galezowsky's own statement, "the results cannot possibly be more satisfactory." In a case which was complicated with lachrymal blennorrhœa, complete re-establishment of normal vision occurred under this treatment—a result thus far never obtained so perfectly under the same circumstances.

New Treatment of Diphtheria.

The application of the galvano-cautery in diphtheria seems to be followed by better results than any other treatment brings about. Especially in those very grave cases where the larger part of the roof of the mouth, the whole soft palate, and most of the pharynx, are covered by the pseudo-membranes, and where, if relief cannot be obtained, the enormous adenoma of the neck, which often develops within twenty-four hours, foretells the inevitable fatal issue, the application of the candescent platina wire appears to do especial good.

Dr. Bloebaum, in Coblenz on the Rhine, has tried this procedure on a considerable number of cases, and communicated the result of his observation to the *Deutsche Medicinal Zeit.*, January 4, 1886. From his article we glean that he endeavors to encircle the false membrane with the platina wire, and the circuit is then closed, while the wire is gradually drawn tighter and tighter until finally the whole deposit is removed. The most remarkable phenomenon about this method is, that whenever the galvano-cautery has destroyed the false membranes, the mucous membrane continues in a healthy condition and no further deposits occur. In all cases where this mode of treatment was carefully carried out, before the great enlargement of the glands of the neck, which is always noted in fatal cases of pharyngeal and buccal diphtheria, had fully developed, the result was a favorable one; no new deposits occurred, and convalescence at once began.

Considering that even the most heroic doses of mercurials and the continuous application of disinfectants, besides systematic feeding and a tonic regimen, are in vain in most cases of the kind referred to, it may well be worth while to give the method in question a more extensive trial; for in all these cases, where death seems but a question of a few hours more or less, every treatment should be resorted to that promises the least aid.

Perityphlitis—Death—Cause—Incarceration of a Melon Seed in the Appendix Vermiformis.

A woman, 30 years of age, entered the Charity Hospital, New York, saying that she had suffered for some time from pain in the caeco-iliac region, and that shortly before admission there was swelling over the gluteal region on the right side.

An examination showed a puffy condition of the gluteal region, but no pus could be found on the introduction of a needle. Within a few days the evidences of pus were so pronounced that an incision was made, when a large amount of fœcal and purulent matter came away, carrying with it some grape-pits. There was no longer any doubt in regard to

the diagnosis. A number of sinuses were found in the gluteal region, and it was the intention to make an opening as near as possible to the perforation of the intestine. The patient was very timorous and declined operative interference. She gradually sank and died in about a month after pus was discovered. The autopsy showed a number of sinuses in the vicinity of the caecum. The appendix was nearly destroyed, but lodged in it was a partly eroded melon seed. The caecum was perforated on its posterior surface. The course of the channel of pus was directly backward, passing over and eroding the crest of the ilium. Had the patient permitted operative interference, this condition might have been discovered, and if so it would have been found that if an opening had been made at the eroded portion of the crest of the ilium, the finger could have been carried down to the caecum and an exploration made. Beyond this, the history of the case and the post-mortem condition did not suggest any operative treatment that would have benefited the patient.

Abscess in the Course of the Spermatic Cord, Simulating Hernia.

It is not always an easy matter to be sure that we have to do with a hernia in a given case, so that we should be prepared to differentiate all conditions that may simulate this trouble. For this reason we reproduce the following case, which Mr. Turner records in the *Lancet*, March 6:

Arthur H., aged 3, was admitted on June 5, 1885, with a tense, hard, non-fluctuating swelling in the inguinal region, not extending into the scrotum. There was no impulse on coughing. Both testes were present in the scrotum. The child was very restless, continually crying; any examination of the tumor apparently gave much pain. The mother had first noticed the swelling the day before admission, and the child was said to have vomited during the night; the bowels were confined; tongue slightly coated. Temperature between 101° and 102°. The child was carefully watched, but after admission there was nothing like sickness. Ice was applied to the swelling, which on June 9 (the fourth day) presented at one spot well-marked fluctuation. The bowels acted naturally on this day. On the following day (June 10) the signs of abscess were well marked. A small incision was made with antiseptic precautions, and about half an ounce of laudable pus was evacuated. The wound had quite healed two days afterwards, and the patient was discharged on June 13. It was discovered after his admission that he had struck himself in the scrotum with a sharp stick about a fortnight previously, and that he had again injured himself by a fall on the day before—*i. e.*, on the day his mother first noticed the swelling. There was no trace of any injury of the scrotum.

Transplantation of the Eye.

A few months ago Dr. Chibret published a plastic operation, which he had performed, which at the time caused a great deal of comment in the secular papers, and which was also described in the Medical and Surgical Reporter, viz., the transplantation of a rabbit eye into the orbital socket of a human being—a girl æt. 16—whose eye had been extirpated.

Chibret now reports the further progress of the case in the *Revue Gén. d' Ophth.*, iv., 9. For about three weeks the patient suffered from severe pains in the transplanted eye and neighboring parts, the abnormal eye became inflamed and suppuration developed, and finally only a small part of the stump remained. Chibret admits that more than once he was ready to enucleate the eye again, as he feared a sympathetic affection of the other healthy eye.

As a resumé of the whole, he says that he shall never try the experiment on the human being again, first, because the result is nihil; then because the transplantation causes a great deal of inflammation and suppuration; next, because the parts are in a worse condition after this procedure than they were before as regards the wearing of an artificial eye; and, finally, because it endangers the other eye. He is, therefore, at least honest enough to admit his mistake, but we cannot comprehend why he recommends further experiments of the same kind (!?) on animals. We mention the whole only to let our readers know the result.

A Tooth Growing in the Nose.

In the *Med. Record*, Dr. E. Hanson Griffin, of New York City, reports the following case:

"Patient, G. I——, aged thirty-two, applied to the Bellevue Throat Clinic, complaining of a sore throat and a pain in the back of the head of two days' duration.

"An examination of his throat showed that there was a cleft of both the soft and hard palate. In examining the upper gum I noticed the root of the second incisor tooth

in the tissue, while an examination of the nose showed the tooth in a perfect state of development projecting from the floor of the nostril upward into the nasal cavity. He said the tooth had been there for years, and gave him no trouble. He never remembered suffering any particular pain when it was growing, in fact did not know anything was the matter with his nose till one day while putting his finger into it he noticed something hard, and looking into a mirror found it to be a tooth. As it gave him no trouble, he did not apply to a physician. He does not think the tooth has grown any of late years. He was a twin, but his sister's throat was in perfect condition, and her nose free from any defect. The patient was opposed to any operation for the removal of the tooth, and as his sore throat was of a trivial character and not dependent upon this trouble, I did not urge a destruction of one of nature's whims."

Spasmodic Contraction of Abdominal Muscles.

Dr. T. M. Rotch reports the following rather curious case in the Boston *Med. and Surg. Jour.*: J. M., a man twenty-eight years of age, presented himself for treatment at the City Hospital, January 12th, 1886. He has always been strong and well, but since beginning to work as a barber last spring, has been very nervous. In April, 1885, he began to have attacks of spasm of the abdominal muscles. The contractions are irregular in force and interval of rest, but have been continuous and have incapacitated him from work; at first he had some control over the attacks, now he has none. The spasms occur nearly every day, and he feels that they are coming on a short time before they begin. The intervals are usually about half a minute. When he has succeeded in controlling one or two spasms, the next one is increased greatly in severity.

He is slightly constipated, and since the attacks began has lost in strength somewhat and had a poor appetite. On physical examination nothing abnormal was discovered. He behaves, when observed during an attack, as though some one had struck him in the epigastrium.

He was treated with Fowler's solution, and on January 21st reported himself as improving.

Case in which Diagnosis was Complicated by a Coincidence.

Dr. Joseph Bell thus writes in the *Edinburgh Med. Journal* for January:

J. M., an ostler, was admitted to Infirmary under my care on 10th November. He had received a severe blow on the forehead, and the side of his head had struck the curbstone. He was insensible; breathed stertorously; blood was oozing from his left ear. He had a severe bruise with much effusion over left parietal eminence, and a distinct deeply depressed fracture of temporal and parietal bones in a line running from the left ear to the bruise described above. I was sent for to trephine him. However, after a careful examination, I came to the conclusion that the sopor was chiefly due to alcohol, and that while the bruise and the ear injury were recent, *the fracture was an old one.* This was received by all present with considerable incredulity, so I put the following case. Use the stomach-pump and shave the head. If the patient is not intelligent in two hours, and you find no old scars on head, send for me again, and I will cut down on the fracture.

The stomach was emptied, and he soon became quite sensible. The head was shaved, and two very large old scars were found, and the patient has made an uninterrupted recovery.

Bromide of Arsenic in Acne.

Dr. Henry G. Piffard, writing in *Journal of Cutaneous and Venereal Diseases*, says:

Conceiving, from purely theoretical considerations, that it might be useful in certain cases, I first tried it in the spring of 1878, in a case of pustular acne vulgaris of moderate severity, and gave it in doses of one milligramme (gr. $\frac{1}{65}$) three times a day. Within a week the patient, a young lady, returned, complaining that her face was much worse. On examination, I found on each side of the face a crop of miliary pustules in addition to the acne. The arsenic was discontinued, and a placebo was prescribed. This was followed by improvement for a week, when the arsenic was resumed in much smaller doses, and in three or four weeks the case was substantially well. In a second case I had a similar experience, and in a third case I prescribed an alcoholic solution, containing one grain to the ounce, and directed that two drops should be taken night and morning. This patient I did not again see for nearly six months, when she informed me that the medicine had, in a few weeks, accomplished all that she desired. Since then I have used bromide of arsenic with much satisfaction in pustular acne, but have not used it in other varieties of this affection, nor in other cutaneous diseases.

An Instance of Remarkable Fecundity.

Dr. Joseph N. Steedy, of Cambridge City, Ind.. reports the following rare case in the *Med. Record:*

On May 3, 1884, he delivered Mrs. S., aged sixteen, of a healthy female child, weighing nine pounds. On February 2, 1886, he delivered the same woman, then eighteen years of age, of three female children. All were born alive, and weighed respectively four and three-fourths, four and one-fourth, and five and a half pounds. The first presented by the vertex, the second by the face, and the third by the foot; each in a separate sac. There was one large placenta, the three cords being attached to the margin at about equal distance from each other. There was about thirty minutes' interval between each birth. These children were born under the most unfavorable circumstances, and with a temperature outdoors of from 10° to 18° below zero. They were all alive at the time of Dr. Steedy's report, and seemed as strong and vigorous as children of their weight usually are when born singly.

Poisoned by Tea.

Dr. Bernstein had under his medical care a whole family suffering from saturnine intoxication. On investigation, he discovered that the poison had been contained in the tea which the family was in the habit of drinking. Prof. Werigo made a chemical analysis, and found not only very considerablo quantities of oxide of lead as a result of his tests, but he also detected larger particles, which were visible to the naked eye. The tea had been bought in Odessa from a firm by the name of J. Ssobel. Prof. Werigo purchased two more packages of tea, each of a half a pound, from the same firm, and found in them two large masses of oxide of lead. He is of the opinion that the presence of the poison in the tea is due to the fact that in China the tea is packed directly into lead boxes, and sometimes in consequence of some peculiar quality of the tea (it perhaps being moist), oxide of lead develops in the form of carbonate of oxide of lead, which, partly as white powder, partly in the form of small leaf-like pieces, becomes mixed with the tea, and it is thus that the poisoning occurs.

Large Bursal Tumors.

The patient, aged fifty-two, blind for the last twenty years, had made his living by letting lodgings. He had done all the scrubbing of the floors himself. He first noticed a swelling on his right knee seven years ago, and a second one formed in front of the left two years ago. Both swellings gradually increased in size; that in front of the right knee had been discharging matter for two years. On admission to the Seamen's Hospital (London) the patient was a healthy-looking man. From the front of the right leg, immediately below the patella, projected a hard rounded tumor eleven inches and a half in circumference. On its outer side was a sinus discharging thin pus. Over the left patella was a fibrous tumor rather more than two inches in diameter. The tumors were removed with antiseptic precautions, and the wounds healed by first intention, with no constitutional symptoms. The tumors consisted of fibrous tisssue concentrically arranged round a small central cavity, and were evidently bursal in their origin.

Chloride of Calcium as a Glandular Deobstruent.

Dr. Arthur Davis thinks that this old and formerly much-used drug, is not sufficiently resorted to in cases of enlargement of the lymphatic glands, and he relates two cases wherein the results were very satisfactory. He utters the caution that the drug must be given in solution in doses of from three to ten grains thrice daily, according to age, and he concludes that in the application of this drug, therefore, three points should be borne in mind:

(1) The necessity of a cautious but gradual increase in the strength of the dose taken.

(2) The steady persistence in its use for a lengthened period.

(3) Its uselessness in cases where suppuration has already commenced.

Absence of One Testicle; Imperfect Development of the Other.

To the New York Pathological Society, March 10, 1886, Dr. Hodenpyl presented specimens from a body in which, on careful search, the left testicle could not be found. The right testicle was of the size of a small almond, and nodular. The epididymis was small. The tunica vaginalis was present on each side, as was also the spermatic cord, terminating on the right side in the rudimentary testicle, and on the left side growing smaller after leaving the abdominal ring, and finally becoming lost. All the elements of the cord were manifest under the microscope. The penis was unusually small, and there was marked phimosis.

Habitual Abortion in Connection with Disease of the Heart and Kidneys.

Dr. Frank H. Murdock, of Bradford, Pa., thus writes to the *Med. Record:*

On February 9, 1886, Mrs. K——, aged forty-one, came into my office complaining of great weakness, and shortness of breath on making any exertion. She menstruated at fifteen, and has always been regular. She married at twenty, and had six living children at term, all healthy. Then followed four premature births, the fœtus dying about the seventh month of pregnancy, and being expelled four weeks later. Next in order came a healthy living child at term, which was succeeded by five premature births of dead children at the eighth month of pregnancy, the last miscarriage occurring three months ago. Examination of the patient revealed a slight laceration of the cervix, a well-marked aortic systolic murmur, and the urine contained albumen a quarter, and an abundance of granular and epithelial casts. There is no history of syphilis, and there is now no tenderness over the sternum or tibiæ, and no changes in the retinæ can be detected.

Prophylactic Measures against Cold.

At a recent meeting of the Société de Biologie, Professor Brown-Séquard read a paper on the prophylactic means to be adopted against accidents resulting from cold, which he founded on the following theory: "The neck is one of the regions of the body the most sensitive to cold; there is no doubt that a great number of accidents, such as coryza, laryngitis, bronchitis, cystitis, enteritis, etc., which are reflex phenomena, result from the impression of cold on the nerves of the skin of the neck." To avoid these accidents, M. Brown-Séquard recommends the blowing on the neck with the bellows of warm air, which should be gradnally cooled, by which means the neck is rendered less sensitive to the action of cold. The Professor found that ten sittings were sufficient to produce effect.

Suture of Nerves in Recent Injuries.

This practice is not, we fear, sufficiently resorted to, and to encourage its practice we report the case which we find in a foreign exchange, of a young man, aged 18, who presented himself with a deep transverse cut an inch or so above the anterior annular ligament; and in addition to the tendons *in situ*, the ulnar and median nerves were found completely severed. The tendons and nerves were sutured with a catgut ligature; and the wound closed, but did not heal kindly. It, however, granulated in course of a few weeks, and about the same time motion and sensation gradually returned; but, as the progress was deemed slow, the application of a mild continuous current was tried, and from this time the improvement was marked and rapid. The patient was able to return to his usual work about seven weeks after the accident.

The Danger from Corrosive Sublimate.

That the use of corrosive sublimate as an antiseptic dressing is not without risk, several published cases testify; and now Dr. H. Keller, of New York, adds another case to the list. After the removal of an uterus, the vagina was washed out with a 1 to 4,000 solution of corrosive sublimate, which had also been used during the operation. On the second day, there were diarrhœa and tenesmus, bloody stools, a small pulse of 156, great thirst, and restlessness. The patient passed bloody urine containing hyaline, granular, and epithelial casts, and renal epithelium; the day after, she died. Dr. Keller thinks that corrosive sublimate should never be used as a disinfectant in cachectic or anæmic individuals, or in those suffering from renal disease.

Treatment of Hydrocele.

Dr. Keyes recommends, in the *New York Medical Record*, the injection of pure carbolic acid "deliquesced in a little glycerine," as a simple, effectual, and almost painless method of treating hydrocele even of large size. The instrument he uses is a glass syringe holding about a hundred minims, to which a hypodermic needle of medium size is fitted as a nozzle. The hydrocele-fluid is first drawn off either through this needle, or by a separate puncture; thirty to sixty minims of the carbolic acid and glycerine are then injected. Dr. Keyes recommends that the patient should be kept quiet, but necessarily confined to bed, for forty-eight hours.

Peculiarities of Malaria in Children.

Dr. J. P. Kingsley, of Missouri, thus sums up the peculiarities of malaria in children: The absence of the chill and sweating stage; the slight periodic fever, which may be detected by the thermometer only; the frequent or periodic pains in the head or epigastric region; indigestion, accompanied with nausea, vomiting, or diarrhœa; the frequent accompaniment of tonsillitis, pharyngitis, or bron-

chitis; the periodicity of the coughing spells, which occur most frequently at night; the necessity of examining the spleen by palpation and percussion; and of giving quinine to confirm diagnosis in doubtful cases.

Aphonia from Morphia.

Dr. Trevelot publishes in the March number of the *Journal de Médecine et Chirurgie* a note on certain effects of morphine. A youth, aged 19, had several attacks of delirium tremens daily. Dr. Trevelot injected under his skin from 15 milligrammes to 2 centigrammes of morphine. After each injection the patient became calmer, the limbs ceased to move and contract, but he was aphonic. This condition lasted for an hour, and reappeared after subsequent injections. The patient became insane, and is now under treatment in an asylum.

To Increase the Urine in Chronic Bright's Disease.

In the *Canadian Med. Record*, Dr. Francis W. Campbell tells us that a liniment of digitalis, iodine, and squills, rubbed over the loins and legs, often increases the urine enormously. It is apt, however, to produce soreness of skin. Cannot be continued long. Sudorifics are useful. Hot-air bath; introduce hot-air under the bed-clothes, free perspiration, then cover with plenty of clothes. Care must be taken not to produce prostration. Dover's powders, liquor ammonia acetatis, pilocarpine, the active principle of jaborandi.

Galium Aparine in Psoriasis.

Dr. T. R. Orwin writes in the *Brit. Med. Jour.* of a woman who had psoriasis of the left hand for upwards of twelve months. She derived no benefit from chrysophanic acid ointment, tar ointment, or arsenic, and was unable to do any housework on account of the painful fissures and general soreness of the affected part. A friend advised a trial of galium aparine to be applied locally as a poultice, and also to be drank as an infusion. In less than three weeks the psoriasis disappeared, and the skin resumed its normal state.

Boric Acid in Cystitis.

Dr. Schidlorsky, a Russian physician, recommends boric acid in the treatment of cystitis, not only as an injection into the bladder in the form of a 2 per cent. solution, but given internally. He recommends a dose of 10 grm. (?) three times a day. He has successfully treated two cases in this way, without observing any disagreeable consequences.

Correspondence.

Rotheln, Scarlatina, and Diphtheria.

Eds. Med. and Surg. Reporter;

Our country is being visited by an epidemic of the above-named diseases—two, or possibly the three ailments, sometimes perplexingly existing in the same family at the same time, and again taking the subject by turns. So, the attending physician may be somewhat confused before he gets through with an ordinary-sized family,

Though the constitutional and local conditions seem distinct in each case, it is scarcely possible for one who observes such intimacy of diseases not to believe that they are in some way related in their pathogenesis. So far there has been but slight mortality; but no doubt later in the season there will be much more.

The *germ theory*, as applicable to lung fever, would also seem much more appropriate in the cases who have died during the past three months, than to the type which usually prevails with us. It seems to have been due to constitutional rather than local causes. The invasion has been less abrupt, the local manifestations in the lung less marked, and more tardy ln their appearance, than is usually the case in croupous pneumonia. There are ataxic symptoms from the inception of the fever, and before the development of hepatization.

Commonly, we have no prodromata in lobar pneumonia, and but little delirium or other manifestations of disordered nervous system, within the first two or three days of the attack. The mortality has not been above the average.

L. N. Davis, M. D.

Farmland, Ind., March 29, 1886.

Inverted Toe-nail.

Eds. Med. and Surg. Reporter:

In March the 6th issue of the Medical and Surgical Reporter, I have read Prof. Agnew's manner of operating in the treatment of inverted toe-nails. I desire to relate the manner in which I treat such cases. After getting the patient under the influence of an anæsthetic, I take the toe in the left hand, run the scalpel, with the back downwards, under the nail, from the end back to the matrix, on a line with the soft

parts, remove the portion slit off by means of the forceps, sear well the matrix that is exposed by means of a probe heated to a white heat, dress the toe with carbolic cerate and lint; in a few days the patient can be around.

I have operated as above described in the last fifteen years, and always produced a radical cure. C. W. Spayd, M. D.

Wilkes-Barre, Pa.

News and Miscellany.

Vanderbilt and the Young Doctor.

Gaillard's Medical Journal says that the following anecdote has been published in one of the New York papers:

A young physician of this city, who had been struggling along in rather an uneasy fashion, was suddenly elated one day, a year or so ago, by a call from Wm. H. Vanderbilt. The young doctor had been a close student, and had won laurels at one of the city hospitals for his surgical work, and in the course of conversation at the Grand Central Depot Mr. Vanderbilt heard the young man's praises, and acting upon a sudden impulse, as was not unusual with him, he went directly from his office down to the doctor's office. He had been suffering for some time from a trouble that many physicians of high repute had treated unsatisfactorily, and now, for the whim's sake, he put himself under the young doctor's care. He was cured quickly, and became an enthusiastic advocate of the young doctor's skill. Many of his friends were sent to the same office, and to-day a big practice, including patients known in the most fashionable circles of New York, enriches the lucky physician whose prospects had been woefully gloomy till the whim of the magnate rescued him from obscurity. But this isn't the point of the story. After it became known that he had treated Mr. Vanderbilt, friends crowded around to explain how he might grow rich. Mr. Vanderbilt was grateful for the cure that had been effected, and all that Dr. X. would have to do, so the acquaintances whispered, was to ask the railroad ruler for a "point" on the stock market, and then through the use of that scoop in a smart little fortune. It was certainly a temptation, for Mr. Vanderbilt had not been backward in his expressions of gratitude. But before he acted on any of these suggestions, he saw Mr. J. Rhinelander Dillon, his personal friend as well as a patient, and asked his advice. "Send in your regular bill," was Mr. Dillon's counsel. "Don't make it one cent bigger than you would to a poor man. Vanderbilt's generous, but he never lets anybody impose upon him. Send in your regular bill; if you try anything else, you'll hurt yourself." The doctor acted on this advice. The bill he rendered was for $50. The check that the next mail brought him was for $1,000.

Increase of Inebriety.

In the last quarterly report of the Washingtonian Home, at Boston, Mass., Dr. Day, the distinguished superintendent, remarks, "that of the one hundred and sixty-five new cases admitted, thirty-four had delirium tremens. The increase of patients each year brings a larger number of cases of disease of the kidneys. Formerly not over one in six cases which came under treatment had disease of the kidneys. Now, one in every three have this affection, which I believe to be owing to the great increase in the use of beer. Many of these cases try to substitute beer for stronger spirits, and in this way tax the kidneys severely. Those who have used beer for years always have diseased kidneys. I am also confident that phases of insanity are more common in the cases which came for treatment during the last four years. My experience sustains the views of Dr. Crothers and others, that inebriety is increasing, and the insane types of inebriety are also increasing. This I believe is due in part to beer-drinking and increased nervonsness. Nothing can be done, practically, until society recognizes the physical nature of inebriety; then its cure and prevention may be expected.

Popular Prejudices Concerning Food.

Decroix, a celebrated officer of the veterinary staff of the French army, recently presented to the Academy of Medicine a memoir relating to the waste of food which arises from the ill-founded prejudices of ignorant persons. He opens up fresh fields for French cooks. It appears from the labors and personal experience of this veteran gastronomist that, when properly prepared, the flesh of diseased animals is perfectly wholesome. He has fed, says the *Therapeutic Gazette*, upon the flesh of beasts that have died of pneumonia, of strangulated hernia, of hydrothorax, cerebral concussion, colic, purulent pyæmia from chronic inflammation of the joints, typhoid pleuro-pneumonia, and even of glanders, acute and chronic.

The naivete which this Frenchman still retains in his old age is remarkable, and we read with much enjoyment how the "*bifteck*" prepared from a horse dead from acute glanders had a taste *sui generis*, which was attributed to the free administration of alcohol to the unfortunate beast.

The results obtained by M. Decroix led him to the conclusion that the meat which is condemned by the Paris slaughter-houses and by the government inspectors might very well be employed for feeding the poor; therefore it is that he has fed upon animals dead of cancer, of phthisis, of fever, of unknown diseases, of pyæmia, and even with great labor he squeezed out, from the reluctant dugs of a cow in the death agonies from contagious typhoid, a little milk, which he drank without suffering. Chickens dead of cholera, pigs dead of various diseases to which hog-flesh is heir, came not amiss to our experimenter; but at last he reached even his limit, and when, on the 25th of November, 1863, he ate the raw flesh of a dog dead of hydrophobia, he confesses that it was "*malgre une grande repugnance*," and that the taste did not altogether please him.

The Disinfection of Rags.

The question of the disinfection of rags has come up at Boston, owing to the protestation of the importers against the restrictions of the Health Board. The views of several experts to whom the matter was referred were expressed as follows: First, that the treatment of rags from non-infected ports is not necessary. Second, that from endemically infected ports rags (1) be disinfected to the satisfaction of the Board of Health before embarkation; or (2) disinfected externally in bulk at the port of entry, and also at the mills after breaking bales; or (3) disinfected after imbaling at the port of entry, at the discretion of the Board of Health. Third, that from epidemically infected ports the importation of rags be prohibited. Some evidence was given to show that the superheated steam process did not in practice always raise the temperature to a point sufficient to kill the germs.

Increase in the Average Length of Life.

The *Popular Science News* for February tells us that a recent writer deduces interesting evidence that the average length of life has been increasing for some time past, from a comparison of ages at death of Yale College graduates early in the eighteenth century and late in the nineteenth. Mr. Dexter's recent volume on the annals of that institution from 1701 to 1745 shows, that of 473 graduates during that period, 153 lived beyond seventy years; that is to say, 32 out every 100. On the other hand, of 672 alumni whose deaths were reported between 1875 and 1885, there were 271 who had passed their seventieth year, or 40 out of every 100. To put it in another way, during the first half of the eighteenth century a graduate stood only 32 chances out of 100 of becoming a septuagenarian, while in the last quarter of the nineteenth century he stands 40 chances out of 100 of reaching that age. The gain in longevity is naturally greatest among educated men familiar with the laws of hygiene, but this showing is hardly more striking than that recently made in England of the extent to which the average of human life has been prolonged within the past 40 years.

Practice in Utah.

A *Weekly Review* correspondent, writing from a small city in Utah, says: "We have here a population of 2500, and of that number there are only three Gentiles and a half dozen apostles. These Mormons are a peculiar people, three-fourths believing in faith cure; *i. e.*, the elders are called, and lay on hands, and if the patient lives they take the credit, and if he dies it is laid to the Almighty, and 'was to be.' The Government has begun to put down this nastiness, and the Mormons are being arrested by hundreds, and, as a consequence, the Gentiles who live in the rural towns are being boycotted.

"There are also a lot of quacks (Mormons) who are in no way qualified to practice, but ply their vocation, only now and then calling in a man of experience when stuck in a labor case. You would actually think, if you lived here, that you were in a foreign country, so un-American are all things, social and professional. A preacher in one of the tabernacles told the people to 'stand firm'—that the Government failed to put them down when they were but hundreds, and now they number thousands, with 100 accessions weekly, and 6,000 births per annum."

The Discovery of Cocaine.

The *Pharmaceutical Journal* says that Senor C. Torretti, an Italian who was formerly professor of chemistry and pharmacology in the Medical Faculty of La Paz, Bolivia, has published a letter in *El Ferro*

Carril, of Santiago, alleging that the honor of discovering cocaine does not belong to Nieman, who is reputed to have first prepared it in Germany, in 1859. It was, he says, isolated in the "humble laboratory of la Boticany Drogueria Boliviana," by his predecessor in the directorship of that establishment, Senor Pizzi, in 1857, at the suggestion of the celebrated Austrian traveler, Tschudy. This he knows to have been the case from manuscripts left by Senor Pizzi, and it can be confirmed by Herr Tschudy and by Dr. Aquiles Reid, an old and well-known resident in Valpariso.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDED MARCH 27, 1886.

Wyman, Walter, surgeon. Detailed as chairman of Board of Physical Examination Officers Revenue Marine Service, March 27, 1886.

Sawtelle, H. W., surgeon. Granted leave of absence for thirty days, March 27, 1886.

Irwin, Fairfax, passed assistant surgeon. Granted leave of absence for seven days, March 22, 1886.

Ames, R. B. M., passed assistant surgeon. Detailed as recorder of Board for Physical Examination Officers Revenue Marine Service, March 27, 1886.

White, J. H., assistant surgeon. Granted leave of absence for three days, March 23, 1886.

Medical Exhibition in Berlin.

An exhibition is to be held in September in Berlin, at which it is intended to preseut a picture of the progress made in recent years in all departments of medical research. The sections will include physiology, pathology, anatomy and general pathology, pharmacology, dermatology and syphilology, surgery, gynecology, ophthalmology, psychiatry, neurology, laryngology, together with military and sanitary affairs. The secretary of the exhibition is Dr. Lassar, 19 Karlstrasse, Berlin, N. W.

Diphtheria and Pigeon-keeping.

At a recent meeting of the Anatomical and Pathological Society of Brussels, M. Destrée called the attention of the members to the fact that cases of croup had been greatly and steadily on the increase in Brussels, so that croup and diphtheria were now endemic there, and he ventured to suggest that there might be some connection between the keeping of pigeons and the occurrence of these diseases. He pointed out that Emmeriels, of Munich, had found the microbe of diphtheria in these birds, and he himself had met with three cases of croup in families where pigeons were kept, in all of which cases signs of the disease had appeared in the pigeons. M. Destrée hoped that members would bear this matter in mind, in order that it might be further elucidated.

Hard on Chicago.

In a case recently brought against Messrs. Fourand Williams & Co., wholesale druggists, of Detroit, by the proprietors of the "California Golden Remedy," of Chicago, the following were the closing sentences of the address to the jury: "You, gentlemen, don't know what a Chicago patent medicine is. You have no idea of the evils and wickedness of Chicago medicine men. Why, gentlemen, when Peruvian bark was so high priced, one Chicago firm actually bought a carload of dried peas, sugar-coated them, and sold them for the best grade of quinine pills. Think of that, gentlemen, and bring in a verdict for the defendant in this case." Verdict for the Detroit firm.

Deaths from Anesthetics in 1885.

The deaths during narcosis in the past year in England have been collated by Dr. E. H. Jacobs, and reported in the *Brit. Med. Jour.* Twelve deaths occurred in chloroform narcosis during an unusually severe list of operations, only four being trivial. The casualties from ether are but three, a small record considering the general use of ether in English surgical centres. No death is recorded from methylene bichloride, or from mixtures of ether and chloroform.

Correction.

MAMMARY CANCER.

EDS. MED. AND SURG. REPORTER:

I am made to say that in mammary cancer "an operation never prolongs life." What I did say was this, that it was very doubtful if, taking the general run of operations for mammary carcinoma, life was materially prolonged.

D. HAYES AGNEW, M. D.

Injuriousness of Natural Gas as a Fuel.

It is thought by some physicians in Pennsylvania, says the *Sanitary News*, that the use of natural gas as fuel is responsible for

many cases of diseases of the respiratory organs. The manner in which it is burned in grates necessitates almost entire closing of these important means of ventilation, and the burning gas also vitiates the air of the room with products of combustion.

Items.

—A statue has been erected in honor of M. Claude Bernard in Paris.

—On March 16, 1886, the French Academy of Medicine voted 10,000 francs to the Pasteur Institute.

—A new publication devoted to the subject of pharmacy has been published at Melbourne, entitled the *Australian Journal of Pharmacy.*

—Venice turpentine in chronic posterior gonorrhœa is highly recommended by the editor of the *American Practitioner and News.* It should be given in large doses.

—A death certificate returned to the proper authorities by a Cincinnati physician gives the cause of death as follows: "She dide with Liver dease & New Monei."

—Notwithstanding Virchow's position in his profession, his sons are said to be very ordinary men indeed. The Germans say that nature broke her mould when he was born.

—In Ceylon the natives cover newly-killed venison with honey, in large earthen pots; these are not opened for three years, and the meat so preserved is said to be of exquisite flavor.

—Dr. J. H. Darey, who has been Resident Medical Officer of the German Hospital, Philadelphia, has been appointed Medical Examiner of the Pennsylvania Railroad Relief Deparcment. His residence is at Erie, Pa.

—The death is announced of Dr. Kazakivich, who had charge of one of the Red Cross hospitals in the Russo-Turkish war. He had written much on medical subjects, and had translated Ludwig's Physiology into Russian.

—Professor von Frisch, of Vienna, a pupil of Dr. Koch, has been appointed to go to Paris and study M. Pasteur's system, at the expense of the committee which has been formed in that city to found an institution for the cure of rabies.

—Eleven cases of cholera, seven of them terminating fatally, are reported to have occurred in the neighborhood of Padua, and three cases, resulting in two deaths, near Rovigno, in Istria. Elaborate quarantine precautions are to be taken previous to the landing at Toulon of the French troops from Tonquin.

—A subscription for the purpose of encouraging researches in the therapeutics of tuberculosis has been opened by the *Gazette Hebdomadaire de Médecine et de Chirurgie,* of Paris. The idea of a subscription for this purpose was suggested by M. Verneuil, and in a few days the sum of over four thousand francs was raised.

—The *National Druggist* says that persons who have a superstitious dread of Friday will not be pleased to learn that this is a thoroughly Friday year. It came in on a Friday, will go out on a Friday, and will have fifty-three Fridays. There are four months in the year that have five Fridays each; changes of the moon occur five times on a Friday, and the longest and shortest day of the year each falls on a Friday. Be careful that you do not sell morphine for quinine on Friday.

—A gentleman who evidently underrates the value of all previous anatomical study writes to *The St. Louis Medical and Surgical Journal* an account of a wonderful case of intestinal obstruction which he finally cured by passing a piece of rubber-tubing up into the rectum just as long as he could shove it in. He says he "passed nearly two yards of tubing into the receptacle," and excitedly exclaims, "What I want to know is, *is* there such a thing as the illiasecle valve?"

—A singular library existed in 1535 at Warrenstein, near Cassel. The books composing it, or rather the substitutes for them, were made of wood, and every one of them was a specimen of a different tree. The back was formed of its bark, and the sides were constructed of polished pieces of the same stock. When put together, the whole formed a box, and inside of it were stored the fruit, seed, and leaves, together with the moss which grew on its trunk, and the insects which fed upon the tree. Every volume corresponded in size.

QUERIES AND REPLIES.

RHUS POISONING.

EDS. MED. AND SURG. REPORTER:

C. E. D., in the last issue of your journal, desires information in regard to treatment of chronic eczema due to rhus poisoning.

I would answer by saying that I had a similar case of over one year's standing, which I entirely cured by applying the galvanic current to the part once daily, and arsenious acid internally after each meal. Cure was completed in six weeks.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to maintain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

RIDGE'S FOOD

FOR INFANTS AND INVALIDS.

Cereal foods are regarded by some with disfavor, as diets for infants, especially by those who maintain the dictum of chemistry in the matter as conclusive. It is urged that as they usually contain a certain amount of unconverted starch, this ingredient, owing to the absence from a baby's saliva of the solvent "*ptyalin,*" must cause indigestion and irritation in its passage through the stomach and intestines. Yet Bouchardat and Sandras have demonstrated that starch, given to animals in excess of what the saliva can act upon, has its granules eroded, dissolved, and transformed into sugar, when it meets the pancreatic fluid in the duodenum. The inference is that the conversion of starch is not wholly dependent on the secretions of the buccal cavity, and that the presence of a limited quantity in an infant's food is not necessarily a source of disorder. Moreover, in dietetic questions the verdict of chemistry can only be received *cum grano salis*; and the final appeal is to practical experience; what might, could, would, or should be, under supposed conditions, loses much of its practical value, when we have easy access to what is.

The preëminent popularity of Ridge's Food has caused it to be singled out for special criticism and attack, and unsparing denunciations have been hurled at it by and on behalf of unsuccessful rivals, whose professed zeal for the welfare and protection of the innocent public would be really touching, if it did not employ the language of disappointment and defeat. Our appeal to the public for its patronage has rested on the excellence of our product; and its full justification is found at this time in an experience of thirty years, during which the sales of Ridge's Food, throughout Great Britain and her Colonies, as well as in every State in the Union, have steadily and largely increased.

Ridge's Food is made from carefully selected winter wheat which, having been reduced to an almost uniform fineness, is thoroughly cooked by a steam baking process. The nitrogenous and phosphatic elements, in which wheat is so rich, are carefully preserved, and a large proportion of the starch is converted into dextrine, while the residue undergoes a further change when the food is prepared, as directed, in the nursery, producing an article of diet at once abundantly nutritious and easily digested. Samples of the preparation will be found alittle sweet and slightly alkaline.

It is claimed for Ridge's Food that it is acceptable to the most irritable stomach of infant or invalid, when used (as sometimes it must be) without milk; and that then it is alone sufficiently nutritive to sustain life.

It is also ammmed that the objections urged against the use of cereal foods in no way or degree apply to our preparation; that the consequences predicted as following such a diet for infants never occur where Ridges Food is used. So contrary, indeed, is the prediction to the results of experience, that an eminent firm of druggists in Chicago, who for many years have sold largely of our preparation write: "Its soothing and satisfying properties are so marked, as often to cause customers to inquire *it does not contain some opiate?*'

We shall be pleased to forward a sample of RIDGE'S FOOD to any physician not yet acquainted with it, who may favor us with their address, satisfied that, with a fair trial, we shall secure his commendation.

Lecture.

ANEURISMS.

BY N. SENN, M. D.,

Of Milwaukee, Wis.,

Professor of Principles and Practice of Surgery and Clinical Surgery, Chicago, Ill.

Delivered at the College of Physicians and Surgeons, Chicago, Illinois.

Reported by William Whitford.

Gentlemen: During our last lecture we aimed to depict some of the textural changes in blood-vessels which predispose the structure to dilatation; in other words, described those pathological conditions which, by disintegration or proliferation of some of the lower elements of the blood-vessels, interfere with the normal adhesion and cohesion of the parts, when another element was added, that is, increased arterial tension, intravascular pressure. We are now prepared from this standpoint to study one of the pathological conditions of the arteries characterized by an increased lumen of a vessel, a condition which we term "aneurism."

I would describe an aneurism as being a swelling containing fluid blood, and in communication with the lumen of an artery, in contradistiction to venous dilatation, where we may have an analagous pathological condition of the vessel from the same cause, resulting in an increased lumen, but the increased lumen taking place at the expense of the entire vascular wall; in other words, the creation of a symmetrical swelling containing venous blood within the normal venous channel.

We shall speak of dilatation of veins in connection with aneurism, but our definition will still hold true, from the fact that the contents of the venous tumor of the dilated vein is still in communication with the open lumen of an artery. By an aneurism, we mean a swelling, not a tumor, containing fluid blood either by an artery or arterial and venous blood mixed, but that this swelling must be in communication with the lumen of an artery.

We shall first describe the different varieties, and will call your attention in the first place to the three distinct varieties as recognized by most authorities. First, the so-called *aneurysma vera* or *true aneurism*, meaning a dilatation of the arterial walls without sacrificing any of its tunics, simply a distension of the arterial tube either as the result of pre-existing degeneration in the vessel, or of localized, increased, intravascular pressure; so that by a true aneurism we mean a sac which, on dissection, presents all the anatomical constituents of the tunics—the intima, media, and adventitia—dilatation having taken place, not at the expense of a loss of resistance of any particular tunic, but a symmetrical dilatation. The next variety is the *aneurysma spurium* or *false aneurism*. By this we mean an aneurism which does not consist in simply dilatation of all the pre-existing tunics, but where the sac is built up of additional structures and elements. Porta claimed that there was no such thing as a true aneurism, and believed that in order to have distension of the arterial tube, we must have destruction of one or more of its tunics. We recognize by aneurysma spurium an aneurism whose sac is made up either entirely of new tissues, or there is so little of the tissue remaining as to be ineffective in resisting intra-arterial ten-

sion. The true meaning of the word is an aneurism as it occurs after traumatism, consequently, aneurysma spurium and traumatic aneurism may be considered synonymous terms. In a traumatic aneurism we have an artificial opening into the arterial tube, the result of a stab-wound, the contents of the artery extravasating into the surrounding tissue, forming an artificial wall, consisting of perivascular connective-tissue, condensed by compression, the new space containing fluid blood, primarily the result of an effusion from the arterial wound, secondary changes in the sac increasing the number of constituents, and when the disease has advanced, results, perhaps, in a sac which may resemble the normal tunics of the vessel—a sac lined by the intima, the result of tissue-proliferation in the new sac; in other words, a granulation process from pre-existing, mature connective-tissue, resulting, first, in embryonal tissue, and finally transformed into endothelial cells. The sac of a traumatic aneurism by the coagulation of blood, mural thrombi serving as a nidus from the tissue from the sac, produces an intravascular thrombus, a cicatricial contraction, which results in an additional element of the aneurism.

The third variety is the *aneurysma mixtum.* We understand by this an aneurism whose sac may be composed of one or more of the tunics of the vessel, the result of degeneration either by sclerosis or atheroma, following endarteritis or mesarteritis, resulting in a circumscribed destruction of the arterial wall, the process being limited to the loss of resistance, the remaining vascular tunic giving away to the normal intravascular pressure, resulting in distension, in the formation of a sac—the true sacculated aneurism.

It is the first and third variety that are usually the result of pre-existing disease of the arterial tunics. A true aneurism affects the segment of the tube, results in a diminution of the resistance on the part of the vascular wall by degeneration of the intima or or media, resulting in a fusiform, elongated dilatation of the artery—the so-called *fusiforma aneuryswa.* Another (third) variety is the result of circumscribed patches, not of the entire lumen of the vessel, but localized, circumscribed patches giving rise to a loss of resistance corresponding to the area of degeneration, a diminution of the resistance over a circumscribed spot, so to speak, a dilatation of the vessel at the expense of the remaining tunic—the adventitia—resulting ing in a distension, localized, symmetrical. The fusiform variety is that which results in a distension of all pre-existing tunics, constituting a symmetrical dilatation of the artery at a particular point, resulting in a loss of resistance of all the tunics, the arterial tension being more mild in the centre, of course; the primary seat of degeneration, having taken place centrally, advances in a peripheral and proximal direction, resulting in the greatest amount of distention at that particular point. As the disease advances, diminishing resistance gradually, we have a shooting of atheromatous to healthy tissue, consequently this form always assumes a fusiform shape. This form being the result of equal pressure on two sides, very rarely results in the formation of mural thrombi in contradistinction to the sacculated variety. It is simply a symmetrical distention, an increase of the lumen in all directions.

A racemose aneurism is that which results in a symmetrical dilatation of the principal artery, with consecutive dilatation of its contributory branches.

We find this disease occasionally about the hand, one of the principal arteries of the finger undergoing a change, the result of a paralytic affection of the nerves supplying that portion of the vessel, or what is more likely, a congenital error of development, either by the original size of the vessel, or by a predominance of tissue in the vessel which predisposes it to dilatation; that is, a misproportion of the histological elements of which the vessel is built up, an increase in loose connective tissue with a defective remained substance between the endothelial cells lining the intima. We have dilatation not only of the entire artery, but of the branches which originate from the vessel. In contradistinction to an angioma, a racemose aneurism increases in size both in a peripheral direction by dilatation in the same manner as a true aneurism, either by a weakening of the vessel wall, by paresis, or by degeneration of the essential elements calculated to resist intra-arterial pressure, resulting in a symmetrical dilatation. Angioma, on the other hand, is a true tumor from a matrix of tissue resulting not only in dilatation of pre-existing spaces, but more particularly in the formation of new vessels. In a racemose aneurism the process is limited to pre-existing channels, the increase in size being in the same ratio as the increase of the principal artery and its main branches.

The circumscribed and true aneurism, in contradistinction to the diffused variety, means, as I have previously stated, a giving away of the tunics of the vessel over a circumscribed space, consequently we miss sym-

metry; it is an asymmetrical dilatation—a sacculation, if you please. When the same process takes place by disintegration or injury of any of the pre-existing tunics, we have a so-called circumscribed aneurism, a mixed form, mixed on account of a loss of one or more tunics of the vessel. For instance, if the intima has been destroyed by sclerosis or endarteritis, the sac is built up of the two remaining tunics—media and adventitia—still remaining a sacculated aneurism.

Mesarteritis is a frequent affection, affecting primarily the media, and by extension and destruction of the middle coat, the intima and adventitia may come together. Consequently, if the principal resisting force inherent in the vessel, and as a result of mesarteritis the muscular fibres, have been destroyed, even a normal intravascular pressure at the point of destruction will result in dilatation of the remaining coats. It is a fact substantiated by post-mortem examinations that in all sacculated aneurisms the muscular fibres have been found peculiarly absent, the pre-existing muscular fibres having been destroyed by mesarteritis. Instead of a reproduction of tissue, which we naturally expect, there is a loss of resistance to counterbalance intravascular pressure, the fibres are not formed, consequently cicatricial contraction takes place between the adventitia and the intima, resulting, of course, in a corresponding diminution of resistance on the part of the vessel tunics. Microscopical examination shows that the muscular fibres which remain by intravascular pressure, become separated, remain as isolated structures in the tunics of the sac, without a tendency to reproduction.

Fusiform aneurism, the result of pathological changes in the vessel, is exceedingly rare.

The sacculated mixed variety is the most frequent of pathological aneurisms.

Another variety is the aneurysma dessicans. By this we mean an aneurism which results from laceration or destruction of one or more of the internal coats, blood extravasating between the remaining coats, dissecting, as it were, the adventitia from the media, forming a mixed aneurism, due either to pathological changes in the vessel tunics or to traumatic laceration.

The last variety, the false aneurism, is always the result of traumatism, and false from the beginning. A true aneurism may be followed by a false one, the result of pathological changes, dilatation takes place, and the sac forms as the result of intravascular pressure. If the true tunics of a sac are in such an atrophic condition as to yield to indirect vascular pressure, extravasation may take place, and we have a false and a true aneurism; but the false is that which results from laceration of all the tunics of the vessel, an extravasation of blood into the connective tissue, the formation of a sac outside of the proper tunics of the vessel. Again, if on account of an injury all of the vessel tunics have been severed, the blood extravasates into the perivascular space by compression and distention, causing a condensation of the perivascular connective tissue which serves as a sac. You would naturally ask if such a condition can be diagnosticated immediately after the injury. The rapidity with which the aneurism forms, the symptoms attending first distention or extravasation, depend upon the character of the wound. We read of cases of wounds in close proximity to the large arterial trunk. We wait for days, and sometimes for weeks, and no symptoms of aneurism appear. A few weeks later a pulsating swelling forms at the site of the wound. You will naturally ask, Why not have the immediate symptoms, if all the tunics of the vessel have been severed?—why we have not immediately extravasation of blood into the perivascular spaces? If the wound is small, a certain amount of blood extravasates, forming a small swelling which may not be appreciable at the time of injury, or even for days weeks subsequently, because by the opening in the vessel as the result of necrosis of the extravasated blood, a thrombus primarily closes the outer lumen of the opening into the vessel, growing by aggregation in a central direction, remaining and closing the wound in the artery, and for the time being preventing hemorrhage. Later, as the result of intravascular pressure, the thrombus is inadequate to co-aptate the wound in the vessel by primary union. Time elapses, cicatrization fails to take place, the thrombus not being infiltrated with proliferation elements, the connective tissue disintegrates and is removed by absorption. As soon as absorption of the thrombus occurs, hemorrhage, of course, results, and following hemorrhage we have a coagulation of fluid blood, in the perivascular tissues, an adherence of all symptoms indicative of a pulsating swelling. The blood still remaining fluid for a considerable time, the coagulation depends, to a certain extent, upon the rapidity of effusion, the area of surface exposed to the circulating fluid, and more particularly upon the size of the opening of the vessel; in

other words, the more the circulation in the perivascular spaces corresponds to the intravascular circulation, the less probability will there be that the blood will coagulate. I mean the rapidity of the current in the false aneurism. If, on account of a predisposition on the part of the connective tissue around the vessel, extravasation occurs extensively at a distance from the wound, and the opening in the vessel is small, the return of blood into the vessel imperfect, coagulation will take place rapidly and extensively. If, on the other hand, the opening is large, and on account of a deposit of connective tissue around the vessel extravasation is difficult, the coagulating process will be correspondingly slow, so that in the majority of cases when extravasation does not follow immediately the infliction of a wound, we may take it for granted that primarily the artery was closed by a thrombus, and the thrombus remained intact; in other words, secondary hemorrhage resulted in the formation of a traumatic aneurism. The remaining form of aneurism may not be the result of a loss of tunics, but of an abnormal circulation between the artery and veins. They are the so-called arterio-venous aneurisms, which effect simultaneously the arteries and veins.

We recognize two principal sub-varieties, the varicose aneurism and the aneurismal varix. By a varicose aneurism we mean one whose sac is located between an artery and vein, as in cases of a sacculated aneurism in close proximity to the vein. If, as the result of atrophic changes from pressure, we have a loss of continuity of the sac of the aneurism, and a corresponding loss to the vein, and consequently an escape of the true aneurism by loss of substance into the vein, we have an aneurismal varix. If we should have a rupture of the aneurismal sac, with an extravasation of blood between the vein and the aneurism, the sac forms between the vein and aneurism as the result of secondary changes from compression on part of the new sac, a destruction of the vein will occur, and a rupture of the vessels of the aneurism in the vein results. An aneurismal varix is that which is produced by an admixture of arterial with venous blood by a direct communication between the artery and the vein, without the interposition of the sac between the vessel tunics. A varicose vein is the result of increased intravenous tension when arterial blood is forced directly into the vein. A pathological aneurism is the result of a diminution of resistance on the part of the tunics of the vessels themselves, of inflammatory changes, or of degeneration of the vessel tunics. A pathological aneurism found in the aged is almost always the result of antecedent degenerative changes affecting primarily the intima, and secondly, the media—a fatty degeneration of the endothelial cells extending from the endothelial lining in a peripheral direction. The disease occurs in patches, circumscribed, well-defined; dilatation takes place at these patches, and results in a distention of the weakened tunics of the vessels in a symmetrical manner—in other words, in a sacculated pathological aneurism. Inflammation, on the other hand, affecting in preference younger individuals, originating in the media, extending from the entire vessel tunic, affecting the entire circumference of the vessel over a limited space, extending in a peripheral and proximal direction, but affecting, at the same time, the entire diameter of the tube, giving rise to a weakening of the vessel wall in all directions, with a yielding on the part of the vessel wall, results in a fusiform aneurism.

Mesarteritis is usually found in persons predisposed to this particular pathological change.

A pathological aneurism of the sacculated variety indicates previous disintegration of one or more of the tunics of the vessel, which by diminishing resistance predisposes the aneurism to dilatation from the normal intravascular pressure. Again, aneurism resulting from paresis of the vessel tunics from imperfect innervation, will result in a yielding of the vessel wall corresponding to the area of paresis.

Traumatic aneurism means an extravasation of blood into the perivascular tissues and the formation of a sac by connective tissue and coagula, recognized early, as the recent observations of Professor Wall prove, by changes in the circulation at the point of injury. If, for instance, we have as a result of gun-shot wound injury of the large arterial trunk, and still have absence of all the symptoms of traumatic aneurism, and we desire to ascertain whether a loss of continuity has taken place at the site of injury, our best method to determine this is to resort to auscultation. Wall has observed that when peripheral symptoms indicate injury to the vessel, if we apply the stethoscope we can satisfy ourselves of a loss of continuity of the intima by a blowing or rasping sound. Auscultation should always be resorted to in suspected cases of injury to large arterial trunks, being careful, however, not to mistake an abnormal sound by compressing the vessel. We can always hear a bruiting if we compress the vessel. This fact was firmly

impressed upon my mind a short time ago when a young physician desired me to examine a man suffering from a subclavian aneurism. He was satisfied he heard a bruiting repeatedly. I applied the stethoscope, but failed to recognize any abnormal sound. Pressing the stethoscope firmly upon the vessel he said he could hear it again. I lifted the instrument and the abnormal sound disappeared. I listened again, but heard no bruiting; but pressing the stethoscope upon the artery firmly I heard a soft murmur—so you must be careful not to compress the vessel. The sound is entirely different when the intima has been ruptured; it is a rasping sound. With such conditions presenting themselves, be careful to reason by comparison, to examine the vessel on the opposite side to detect the difference, satisfying yourself that by compression of the vessel you simply elicit a soft sound, while the earliest symptoms of traumatic aneurism cause a loss of continuity of the intima, resulting in a roughening of the lining of the vessel, giving rise to a rough sound.

In considering predisposing causes, more particularly in traumatic aneurism, it is important to remember the location of the vessel. Of 561 cases reported by Crisp, we find in 308 the aneurisms were located in regions amenable to operative interference. Again, of the 308 cases of external aneurism, he found 137 were located in the popliteal spaces, showing conclusively that arteries which are most exposed furnish the largest percentage. Of 561 cases, the ophthalmic artery, being so well protected, furnished only one case. It is not only the exposure to direct violence which predisposes to aneurism, but it is the particular location and surroundings of the vessel. A vessel surrounded by firm, muscular bundles, giving adequate lateral support, is less likely to furnish a case of aneurism; but a vessel surrounded by less adipose tissue is more liable to yield to abnormal intravascular pressure; consequently, vessels located in the popliteal spaces, surrounded by a bed of adipose tissue, are the vessels most likely, under exciting causes, to result in dilatation. An artery which is so liable to undergo a relative change between adjacent tissues is predisposed to aneurism, consequently, as a rule, they are located at points corresponding to flexion and extension. For instance, aneurisms about the hip-joint, in Scarpa's spaces, about the popliteal artery, and about the bend of the elbow. An important element in considering the influence of traumatism as it affects the arterial tunics is the peripheral or proximal point of fixation. As long as an artery by changing its relative position by flexion and extension remains unfixed, loses all virtue of its elasticity, its tunics are but little affected, but if it remains fixed, and by hyper-flexion and hyper-extension the vessel is extended, it constitutes a most important predisposing cause.

The largest percentage of pathological aneurisms is furnished by the aged from the well-known cause of atheromatous degeneration and sclerosis—causes inherent in the patient and the vessel itself, so that the least exciting cause in the nature of traumatism, determining an increased afflux of blood to a part, causes intravascular pressure, which, by coming in contact with the weakened vessel, will result in dilatation. Traumatic aneurism is most frequently met with in people from thirty to forty years of age, in people in the prime of life, who by the nature of their occupation are predisposed to injuries, consequently, occupation acts as a predisposing cause. Statistics tend to show that aneurism, as a rule, occurs with the greatest frequency in large cities—most frequently in England and Holland—and more especially in people who are engaged in car-loading, ship-loading, etc. Gross has made the observation that in America aneurism is an exceedingly rare affection; rare because our nation is young, because the atheromatous degeneration as the result of imperfect health, of unfavorable sanitary or hygienic conditions, is still in its infancy. In this country most cases of aneurism seem to occur in New York.

In the ætiology let us consider the effects of sclerosis as affecting primarily the intima, producing an increased proliferation of tissue elements, unattended by an increase of physiological function. The process of proliferation is invariably followed by degeneration—a sclerosis resulting in a thickening of the arterial tunics, indicating the extent to which degeneration has proceeded—a sclerosis, first, diminishing the calibre of the tube by central proliferation, extending in a peripheral direction, invading gradually the tissues, infiltrating the media, displacing pre-existing normal muscular fibres by a neoplasm, followed subsequently by degeneration of the products of proliferation, a condition which precedes and excites atheroma.

In describing the changes in the sac, I will call your attention to pressure atrophy not only as it involves the sac itself by over-extension on the part of increased intravascular pressure, but pressure atrophy as it affects surrounding tissue. The sac of an

aneurism will become distended in proportion to its inability to maintain the necessary amount of resistance; consequently, if an artery is deeply located, surrounded by unyielding tissue, the danger from over-extension and rupture of the sac is diminished in proportion to the amount of lateral support furnished. If the vessel is situated superficially with inadequate lateral support by distention, there is greater risk of rupture. Again, as far as the sac itself is concerned, if, as the result of a mural thrombus, it is strengthened, and the mural thrombus serves as a nidus for proliferation tissue, the amount of resistance on the part of the sac increases with the amount of proximal cicatricial tissue formed in the coagulum as a result of infiltration of the thrombus by proliferation from mature connective tissue surrounding the sac; consequently, it is that form of aneurism most likely to give rise to early atrophy, where coagulation fails to take place. An aneurism may remain in a latent condition for an indefinite period, if the normal process of regeneration of tissue in the interior of the sac is not interfered with, but favored by the formation of a mural thrombus. If the sac furnishes conditions unfavorable to the formation of a mural thrombus, dilatation of the vessel is more likely to take place early, if no firm muscular or bony support interferes with it. Extrinsic atrophy is the result of atrophy outside of the sac, and may affect all of the tissues without regard to their anatomical constituents. In aneurism of the thoracic aorta we may have all the evidences on post-mortem examination of so-called caries the result of pressure atrophy, resulting in osteoporosis, following which we may have degeneration of the bone constituents, and their removal by absorption. Coagulation in a sac, like in any other condition, means necrosis of the blood. It is not influenced by the condition of the internal surface of the sac, but by the amount of intravascular pressure. It is a well known physiological fact that as long as the blood current remains intact with the normal vessel tissue, and the *vis a tergo* is not materially diminished, coagulation will fail to take place. If the circulating blood is brought in contact with a deteriorated intima, with products of degeneration, coagulation is favored correspondingly. If the intima has become degenerated as the result of endarteritis, sclerosis, or atheroma, with a normally smooth lining, a mural thrombus is determined; consequently a second factor is a diminution in the blood current, determined, to a certain extent, by the character of the sac and the opening which communicates with the vessel. If we are dealing with a narrow sacculated aneurism, interfering with the return of blood from the sac, coagulation is favored. Inflammation is a dangerous phenomenon. It may possibly result in a favorable issue, but by affecting the tissues of the sac wall itself, without giving rise to suppuration, to disintegration, and determining rupture where the aneurism is located in a large vessel, it means almost immediate death. Occasionally, however, if the inflammation remains within due bounds, and does not materially interfere with the normal constituents of the sac wall; if, on the other hand, the inflammation in a central direction is attended by a process of restoration, it may lead to a favorable issue.

The symptoms and diagnosis of aneurism are subjects of the greatest importance.

The first and one of the most reliable symptoms is pulsation—a pulsation in the swelling synchronous with the action of the heart. This is an important feature. A tumor situated upon a large vessel may and does pulsate, but the pulsations are felt only in one direction, away from the vessel. An aneurism pulsates in all directions. That is the distinctive feature. If, for instance, a malignant tumor located upon the aorta pulsates in an anterior direction, if the aorta is the seat of an aneurism, you can palpate and isolate, as it were, and the pulsations are felt in all directions alike, showing there is a symmetrical and not an asymmetrical dilatation. You must differentiate between tumors located upon a vessel and an aneurism. Always test the effect of pressure. An aneurism accessible to direct palpation becomes diminished on direct pressure. It becomes smaller because you diminish the contents of the sac. This test is especially applicable in aneurisms devoid of mural thrombi. Auscultation is resorted to, to ascertain the existence and absence of a bruiting or blowing sound heard synchronous with the heart's action. There are as many different kinds of sounds produced by aneurisms as there are aneurismal sacs. The sounds differ in proportion to the size of the sac, the rapidity of the current, and the size of the opening of communication between the vessel and the artery; but the bruiting heard synchronous with the action of the heart means an abnormal circulation at the point of auscultation, differentiated from stenosis of the vessel by its roughness.

The differential diagnosis must be carefully considered. In all tumors occurring in locations where aneurisms are likely to

develop themselves—all swellings about the region of the neck, in the popliteal spaces, in Scarpa's triangle—especially tumors which by compression of the vessel will give rise to some of the symptoms of aneurism, and more particularly cases of abscess attending an aneurism (a mistake that has been so often made). In case of an abscess accompanying an aneurism, the abscess may not be in direct communication with the aneurismal sac, but suppuration may take place outside of the sac; but opening of the abscess may determine rupture of the aneurism by diminishing the necessary lateral support, consequently if you still remain in doubt there is only one more diagnostic measure, and that it is to resort to direct exploration, and satisfy yourself as to the contents of the swelling. If you find on inserting an exploratory syringe you have entered a hollow space, and on withdrawing the piston you find pus, you must necessarily conclude that the entire swelling is made up of this purulent collection super-imposed between the skin and the aneurism. In all cases of great doubt, follow the exploratory puncture and remove the purulent collection. You will then determine how much of the swelling remains between the aneurism and the skin, which can leave no further doubt as to the presence of an aneurism.

Communications.

FŒTAL PSYCHOLOGY.

BY THOS. S. SOZINSKEY, M. D., PH. D.,
Of Philadelphia.

"We may fairly assume from analogy that a long time before it is born a child will have become acquainted both with pain and pleasure." Thus it is said on page 7 of an excellent little work by M. Bernard Perez, a translation of which, with a flattering introduction by the distinguished English psychologist, James Sully, has just been published, entitled "The First Three Years of Childhood." The question is not only curious, but highly interesting, especially to physicians. If an unborn child may experience both pleasurable and painful sensations, the fact should be more widely known than it seems to be. I am of the belief that medical graduates are oblivious of it. I am pretty sure I never had it brought to my attention in a lecture on obstetrics.

M. Perez is by no means a visionary theorist; on the contrary, he is a patient, sharp observer, and in full sympathy with the modern scientific school of philosophy. Mr. Sully remarks of him that he "combines considerable physiological and psychological knowledge with a practical interest in education." What he may have to say is certainly entitled to respectful attention. To be sure, he is not a physician; but it may not be doubted that a practical educationist may be quite familiar with the facts of psychology. Still, there are some statements in M. Perez's book which he would hardly have made had he been an accoucheur. Thus, says he, "there is no doubt that the moment when the infant first enters into relation with external realities is a very painful one." (Page 7.)

Of very ancient date, indeed, is the belief that unborn babies may experience pleasure and pain. There is a well-known passage of Scripture (St. Luke i. 44,) illustrative of it. It is upheld by many theologians, as well as "old ladies" and others at the present day.

Notwithstanding the positive statements of M. Perez and others, I think nearly all physicians hold that intra-uterine life is a blank mentally. Before birth, a child can experience no sensation whatever, either pleasurable or painful. There is no fœtal psychology. So the doctor is apt to think: but can he present sufficient reasons for his belief?

The question is really an open one, I believe. That an unborn child is alive is certain. It is equally certain that without nerve-centres in full play there could be no pulsation of the heart or any other action of the child's economy. No doubt all pre-natal activities may be very reasonably classed as reflex; but there is no very evident reason why the cerebral activity on which consciousness depends should not at times exist, at least toward the end of the period of gestation.

Is there no stimulus to excite consciousness in the fœtal brain? There is sufficient ground for believing that if the brain were without external connections there could be no mental activity within it; without the special senses there could be no mind. In the fœtus the senses of sight, smell, taste, and perhaps hearing, are entirely dormant, but what of touch, or rather general sensibility? May not a marked disturbance of function or impression made on the skin of a fœtus be productive of consciousness? I believe all the necessary conditions of nerves and brain are present in the later months of fœtal life. Is it reasonable, then, to declare consciousness in the fœtus, at any time, to be impossible?

But from what we know of the degree of sensibility of new-born babies, it is highly improbable that vivid consciousness is possible in the fœtus, even at term. In general, there is but little chance during intra-uterine life for decided local impressions to be made; and most of such, it may be observed, point to pain. Jars and other rude impressions are only occasionally experienced, and it is only from these likely that the production of any degree of consciousness is at all probable. During labor the pressure experienced by the head is usually sufficient to effectually preclude any possibility of consciousness being aroused; and hence birth cannot, as a rule, be a painful process.

Thus much for the present on the subject of fœtal psychology. It is of enough importance, I believe, to receive some attention from medical men.

REMOVAL OF A SPLINTER OF WOOD FROM THE ORBIT.*

BY HIRAM WOODS, M. D.,

Of Baltimore.

Assistant Surgeon at Presbyterian Eye and Ear Hospital.

The lodgment of a large foreign body within the orbit, without inflicting damage upon the eyeball, is an accident of rare occurrence. The following case came under my care in October, 1884:

W. H., Jr., 12 years of age, was brought to me on account of an "abscess in his lower lid." His father told me that *six weeks* previous to his visit, his little boy was playing about a house in process of building, when he was struck in the face by a piece of shingle thrown obliquely from above. The boy was looking up at the time. The father pointed to an open wound in the lower lid of the left eye, just below the margin of the tarsal cartilage, and about two lines from the external orbital angle, and told me that this opening had been there since the day of the accident. The boy ceased to complain of pain after two or three days, but this wound did not close. About two weeks before the boy was brought to me, pain had returned, and with it there was considerable swelling of the lower lid. Poultices had been applied, and I found a copious discharge of pus from the original wound, and from a second small opening lower down and nearer the centre of the lid. I thought I could feel a foreign body under the conjunctiva, but the father was sure that no splinter had entered the orbit. The wound was painful, and the boy would not allow me to use a probe. The following day Dr. C. A. Cook kindly came to my office and gave bromide of ethyl for me. On passing the probe into the more external of the two wounds, I felt the splinter lying on the floor of the orbit. It was easily removed after I had enlarged the original wound, and measured a little over one inch long and one-fourth inch thick. I did not re-introduce my probe, as the effects of the ethyl had passed off by the time I had removed this piece, and I did not care to renew the anæsthesia. The wound, however, did not heal, and one week after my first operation, I re-examined the wound under ethyl. After a careful search, I found a small piece of wood less than a third of an inch long, and as thick as the end of a lead-pencil, near the internal angle of the orbit. This was removed, and the boy soon got perfectly well. I saw him last summer. There is a linear scar in the folds of skin of the lower lid, but there is no ectropion. The motions of the eye-ball are unimpaired.

Small foreign bodies, as shot, pebbles, etc., are occasionally embedded in the orbit and remain there indefinitely, doing no harm at all. Some curious cases are reported in which the foreign body remaining in the orbit, and causing no trouble, has been of great size. Soelberg Wells and Juller each mention the case, first reported by Mr. Brudenell Carter, of a hat-peg three and three-tenths inches long entering the orbit and causing no trouble for about twenty days, when it was drawn out through the orbit. The case is narrated more fully in Lawson's "Injuries to the Eye, Orbit, and Eyelids." The supposition of the surgeon who saw the case seems to have been that the head of the peg entered "the antrum of the opposite side." There was certainly not room enough for it in the orbit.

By far the more usual sequel of a foreign body entering the orbit is the occurrence of orbital cellulitis or periostititis. If the inflammation involves the deep orbital cellular tissue, there may be, after the formation of pus, protrusion of the eyeball, impairment of the motives of the eye, and optic neuritis, from the great pressure to which the nerve is subjected.

In removing the foreign body Soelberg Wells thinks that it is generally better to make an incision through the *conjunctiva* than through the skin of the lid. This is to avoid the ectropion which might follow the contraction, taking place during the healing

*Read before the Baltimore Academy of Medicine, March 16, 1886.

process. In the case I have narrated above, the two openings *already* in the skin made it unnecessary to open the conjunctiva.

Medical Societies.

THE PHILADELPHIA NEUROLOGICAL SOCIETY.

Stated meeting, February 22, 1886. The President, S. Weir-Mitchell, M. D., in the chair.

Dr. Harrison Allen read a paper on

The Headaches which are Associated Clinically with Chronic Nasal Catarrh.

Dr. Carl Seiler said that we all know that there is more or less headache associated with nasal catarrh, but how far exact lesions give rise to these exact pains, had not before been described in so many words. He thinks, with Dr. Allen, that the headache of reflex origin is largely due to pressure upon one of the surfaces of the nasal chambers. It is a curious fact, in his experience at least, that in most cases the headache of catarrh occurs on the left side of the head; while, on the other hand, obstruction of the right nostril is much more common than that of the left. He has observed several cases in which the pain was referred to the teeth and to the ear, which, as Dr. Allen has remarked, is very rare. He remembered three cases which came under his notice lately. Two of these patients complained of toothache, or rather of a peculiar pain in the upper jaw, which might be called toothache. After careful inspection by skilful dentists, the teeth were pronounced perfectly sound, and local applications for the relief of the catarrh also relieved the toothache. The third, a lady, complained of intense pain in the left external meatus, quite deeply situated. In this case applications to the meatus had no effect, but the pain was entirely relieved by local treatment directed to the nose. In neither of these three cases was headache present.

Dr. S. Solis-Cohen said that Dr. J. Solis-Cohen had once told him of a book written by a charlatan, who had discovered the connection between nasal catarrh and headache, and had been quite successful in his treatment of such cases. He had not been able to find the reference to this book, but he had come across a reference to a paper in an early number of the *American Journal of Medical Sciences*, vol. v., describing a case of periodical hemicrania relieved by the expulsion of a calculus from the nose. This is referred to only in relation to the history of the subject. As to the thesis itself, his personal experience is not extensive; but he has seen in the practice of J. Solis-Cohen a large number of cases in which headache was associated with and frequently dependent upon diseased conditions of the nasal passages, and in which relief followed the cure of the local affection. He had not before heard the subject presented in the systematized way in which Dr. Allen had treated it, and consequently was not prepared to discuss his classification.

Dr. Harrison Allen said that Dr. Seiler's remark on the connection between earache and chronic nasal catarrh interested him very much. We are not yet in possession of all the facts necessary to explain this connection. He was glad that Dr. Cohen had referred to the case of nasal calculus. The cases recorded by others were not mentioned in his paper, since he lacked the necessary time thoroughly to look up the literature. He believed that the subject of headache which is found associated with chronic nasal catarrh, has never been separately considered, nor the differential diagnosis between it and other forms of headache presented. It is well known that the majority of headaches are much alike. As stated in the paper, the brow, temporal, vertex, and occiput are so commonly involved in all headaches that patients do not distinguish between the several sources of pain, and physicians themselves may occasionally be so far misled as to fail to determine the exact cause of the ailment. In all obscure cases of distress about the head, the nasal cavities should be carefully examined.

Dr. Charles K. Mills, at the request of Dr. C. P. Henry, of the Insane Department of the Philadelphia Hospital, exhibited

A Case Presenting Cataleptoid Symptoms, the Phenomena of Automatism at Command, and of Imitation Automatism.

This patient had been recently admitted to the hospital, and no previous history had as yet been obtained. He was a middle-aged man, not unintelligent looking, and in fair physical condition. His condition and his symptoms had remained practically the same during the short time that had elapsed since admission. He remained constantly speechless, almost continually in one position, would not open his eyes, or at least not widely, would not take food unless forced, and his countenance presented a placid, but not stupid or melancholy appearance. He

had, on several occasions, assumed dramatic positions, posing and gesticulating. It had been discovered by Dr. Henry that the patient's limbs would remain where they were placed, and that he would obey orders automatically. The case had been regarded as probably one of katatonia, but in the absence of previous history it was not known whether or not he had passed through the cycle of mania, melancholia, etc., which constitutes this fully developed disease. He had had, since admission, attacks of some severity, probably, from description, hystero-epileptic in character.

Dr. Mills, in exhibiting the patient, first placed his arm, and legs, and body, and head in various positions, where they remained until he was commanded to place them in other positions. His mouth was opened, one eye was opened and the other was shut, and he so remained until ordered to close his mouth and eyes. In most of these experiments the acts performed were accompanied by remarks by Dr. Mills that the patient would do thus and so as he was directed.

Various experiments to show automatism at command were performed. Dr. Mills, for instance, remarked that the gentleman was a good violin-player, when the patient immediately proceeded to imitate a violin-player. In a similar way he took a lead-pencil, which was handed to him, and performed upon it as if it were a flute. He danced when it was asserted that he was an excellent dancer; placed his arms in a sparring position, and struck out and countered, on telling him that he was a prize-fighter; went through many of the movements of drilling as a soldier, such as "attention," "facing," "marking time," "marching," etc. He was told that he was a preacher and must preach, and immediately began to gesticulate very energetically as if delivering an earnest exhortation. He posed and performed histrionically when told that he was an actor, etc. He was given a glass of water and told that it was good wine, but refused to drink it, motioning it away from him. He was then told that it was very good tea, when he tasted it, evincing signs of pleasure. During all these performances he could not be induced to speak; his eyes remained closed, or, at least, the eyelids drooped so that they were almost entirely closed. He showed a few phenomena of imitation, as keeping time, and marching to the sound of the feet of the operator, etc.

After exhibiting these phenomena, Dr. Mills made the following remarks:

This patient is undoubtedly suffering from some form of mental disorder. The case is probably one of those which would be classed under the head of katatonia, although in the absence of a past history, I do not think that I am entirely justified in making this diagnosis. In the affection known as katatonia, first described by Kahlbaum, and in this country discussed by Hammond, Spitzka, and others, but most ably and fully by Kiernan, alternate periods of mania, melancholia, and, it is said, cataleptoid states, are present.

Taking the patient as we find him, I have no doubt several views will be suggested to those present. One of the first thoughts that would suggest itself to any one is that the man is simulating. This idea, I believe, can be dismissed. He is, so far as we have been able to determine, a genuine case of mental disorder, the phenomena which have been exhibited here this evening constituting an essential portion of the psychical affection. Many here present, however, are trained in the observance of mental and nervous manifestations, and I would like to hear from them as to the nature of the case.

Taking up the phenomena themselves in detail, let us question ourselves as to their nature. Have we here genuine catalepsy? What constitutes catalepsy? What are the pathognomonic symptoms of this ancient but not well-understood affection? I have recently been interested in the subject of catalepsy, and I find some want of clearness in authorities as to its distinctive differential features. Rosenthal and some others would make waxen flexibility the *sine qua non;* in its absence regarding the case as not one of genuine catalepsy. Waxen flexibility and unconsciousness of surroundings are the two points upon which most stress is laid by the majority of well-known writers. What is to be understood by waxen flexibility? I take it that it is a symptom which shows itself in the following way: A patient's leg, or arm, or fingers, his head, or his trunk, on being placed without command, or without remark, by the operator in any special position, will there remain as long as it is possible under ordinary physical laws for it to continue in that position. Such limb or part can be moulded like wax or lead into every possible shape, and will there remain independently of or in spite of commands to the contrary. The true cataleptic patient, according to this conception, is in such a condition as to consciousness that he is not capable for the time being of understanding or of obeying a command. So far as mentality is concerned, he is a genuine "wax figure." This, in my opinion, is a very rare

condition. I have sometimes almost doubted its existence. I have certainly seen very few cases which would answer to the picture which I have tried to draw.

Certainly, waxen flexibility, as I have thus described, is not present, or at least not always present, in this patient. It is true that even when I say nothing, his limbs will sometimes remain in the grotesque positions in which they are placed; but he is not in a strict sense unconscious of what is being done. The very movements of my hand, my appearance (for these patients do see, although their eyes are partly closed), may in this peculiar frame of mind suggest to him my wishes. I am inclined to think that many of the cases reported as examples of catalepsy are, in reality, cases which present phenomena analogous to those shown by this man.

These phenomena are those which have for many years been known and described under various names. I well remember, when a boy, attending a series of exhibitions given by two travelling apostles of animal magnetism, in which many experiments similar to those exhibited this evening were performed upon individuals selected, apparently, at hap-hazard from a promiscuous audience, these persons having first undergone a process of magnetizing or mesmerizing. In the experiments of Heidenhain, of Breslau, upon hypnotized individuals, many similar phenomena were investigated, and described and discussed by this physiologist under the names of "automatism at command," and "imitation automatism." The hypnotized subjects, for instance, were made to drink ink, supposing it to be wine; to eat potatoes for pears; to thrust the hand into burning lights, etc. They also imitated all manner of movements possible for them to see, or to gain knowledge of by means of hearing, or in any other way. They behaved like imitating automatons, who repeated movements linked with unconscious impressions of sight or hearing, or with other sensory impressions. It was noted in the experiments of Heidenhain, that the subjects improved with repetition. I am inclined to believe that the patient before us performs better to-day than he did yesterday, or the day before. His manifestations, although, in my opinion, not simulated, have been improved somewhat by practice. Charcot, Richer, and their *confrères*, have made similar observations on hysterical and hypnotized patients, which they discuss under the name of "suggestion."

Hammond (Med. and Surg. Reporter, vol. xlv., Dec. 10, 1881,) suggests the term "Suggignoskism" from a Greek word, which means "to agree with another person's mind," as a proper descriptive designation for these phenomena. In referring to persons said to be in one of the states of hypnosis, he says that he does not believe that the terms hypnotism and hypnosis are correct, as, according to his view, the hypnotic state is not a condition of artificial somnambulism; the subject, he believes, is in a condition where the mind is capable of being affected by another person, through words, or other means of suggesting anything. In the clinical lecture during which these opinions were expressed, Hammond is reported to have performed on four hypnotized young men experiments similar to those which have been exhibited this evening upon this insane patient. His subjects, however, were not cases of insanity. A bottle was transformed by suggestion into a young lady; sulphur was transmuted into cologne; one of the subjects was bent into all sorts of shapes by a magnet; another was first turned into Col. Ingersoll, and then into an orthodox clergyman, etc. In reading such reports, and in witnessing public exhibitions of the kind here alluded to, one often cannot help believing that collusion and simulation enter. Without doubt, this is sometimes the case, particularly in public exhibitions for a price. What has been shown here this evening with this man mentally afflicted—what has been shown again and again by honest and capable investigators of hypnotism—prove, however, not only the possibility, but the certainty of the genuineness of these phenomena in some cases.

Dr. H. C. Wood did not see that this case is closely allied to catalepsy. He had never seen a case which he considered genuine, thorough catalepsy. He had seen a number of cases occurring in the somnolent state or cerebral syphilis and various other disorders, in which there was a tendency to catalepsy—of course, using the term in its narrow sense. He believed this to be simply a case of automatism at command. He noticed when Dr. Mills raised the hand, that the man moved his hand rather by his own effort than by permitting it to be lifted by the doctor. This shows that the man interprets the muscular movement just as he interprets the command to march. The apparent catalepsy is simply the result of the command. He had seen exactly the same condition in a child two or three years of age under the care of Dr. de Schweinitz. The child could be placed in any position, and would stay there almost indefinitely. He

could see very little relation between this and true catalepsy. This is a psychical condition, while catalepsy is probably a disease involving lower nerve centres than are affected in this man.

Dr. Hobart A. Hare said with reference to Dr. de Schweinitz's case, that it exhibited more of the lead-pipe character than does this one. When the attempt was made to move a limb, it moved in a stiff way. One of the peculiar positions in which the child was placed was to seat it on the floor with the head and feet pointing toward the ceiling. It would remain balanced on the coccyx for some time, until it fell over exhausted.

The President preferred to accept the German definition of catalepsy, as given by Dr. Mills. In his lifetime he had seen two cases—one for but a few moments before the condition passed off. The other was most extraordinary. Many years ago he saw a young lady from the West, and was told not to mention a particular subject in her presence, or very serious results would ensue. He did mention this subject, rather with the desire to see what the result would be. She at once said, "You will see that I am about to die." The breath began to fail, and grow less and less. The heart beat less rapidly, and finally he could not distinguish the radial pulse, but he could at all times detect the cardiac pulsation with the ear. There was, at last, no visible breathing, although a little was shown by the mirror. She passed into a condition of true catalepsy, and to his great alarm remained in this state a number of days—something short of a week. Throughout the whole of this time she could not take food by the mouth. Things put in the mouth remained there until she suddenly choked and threw them out. She apparently swallowed very little. She had to be nourished by rectal alimentation. She was so remarkably cataleptic that if the pelvis were raised, so that the head and heels remained in contact with the bed, she would retain this position of opisthotonos for some time. He saw her remain supported on the hands and toes, with feet separated some distance, with the face downward, for upward of half an hour. On one occasion, while she was lying on her back, he raised the arm and disposed of the fingers in various ways. As long as he watched the fingers, they remained in the position in which they had been placed. At the close of half an hour, the hand began to descend by an excessively slow movement, and finally it suddenly gave way and fell. Not long after this she began to come out of the condition and quite rapidly passed into hysterical convulsions, out of which she came apparently well. He was not inclined to repeat the experiment.

Dr. James Henry Lloyd related the following case: A male patient, about twenty-five years of age, presented himself at the Nervous Dispensary, University Hospital, with a history of masturbation, and was then suffering with a consequent sexual hypochondria. His manner and facial expression indicated profound melancholia. He told his story with difficulty, and tended constantly to lapse into silence and brooding introspection. While a relative, who accompanied him, was relating some details of the case, the patient was observed to fasten his eyes steadily on the blank wall and remain in a fixed attitude. On seizing his arms and elevating them above his head, they were found in a condition of true "lead-pipe" flexibility, with prolonged persistence in the positions in which they were passively fixed. At the same time the patient was apparently unconscious or unmindful of the experiment; and even required a loud call, accompanied with a decided nudge, to bring him to himself. The case throws some light, possibly, upon the psychology of these interesting conditions. This patient was no doubt in an exaggerated state of what is usually called "abstraction of mind," which all persons experience in minor degrees. He was absorbed in his melancholy reflections, and oblivious to peripheral impressions. Subsequent observations failed to discover him in this condition.

Dr. Henry said that the idea of simulation in this case, as has been stated, can unquestionably be dismissed. Before any conceivable motive could be ascribed, the actions were more marked than to-night. Since his admission, five or six days ago, he has quite spontaneously assumed various attitudes—dramatic attitudes, attitudes of prayer, etc. In moving the man's limbs there is a considerable of the "lead-pipe" element brought out.

Another feature of the case is that the man has had peculiar convulsions resembling epilepsy. He, however, has not lost consciousness. By vigorous shaking and calling, he could be recalled to himself, but his face is absolutely apathetic, and to all appearances he is unconscious; he also refuses to eat, which agrees with the classical descriptions of katatonia; he has to be fed either artificially, or through the fear of artificial feeding, after the nasal tube has been resorted to once or twice, he will take food without it.

NEW YORK ACADEMY OF MEDICINE.

Regular meeting, January 21, 1886.

The President, A. Jacobi, M. D., in the chair.

Reflex Symptoms in Nasal Affections.

Dr. Emil Gruening opened the discussion with a brief paper on reflex ocular symptoms in nasal affections. There were a number of cases, he said, in which ocular symptoms existed, such as sensitiveness to light, lachrymation, redness of the conjunctiva, which measures directed toward the eye, failed to relieve, but which disappeared almost immediately upon instituting nasal treatment. Of course, not all eye affections, the cause of which was not quite apparent, would yield to treatment directed to the nose, but he still had a list of 150 cases in which the result of the treatment went to confirm the view that there was an intimate relation between the disease in the nose and that in the eyes. The nasal treatment would depend upon the affection present. In some cases there was only a slight catarrhal appearance of the Schneiderian membrane, and in others nothing abnormal could be discovered, yet treatment directed to the nose resulted in a disappearance of the ocular symptoms. Dr. Gruening did not include among these cases those in which the eye disease could be accounted for by direct extension of the nasal disease up the lachrymal canal.

Dr. Thomas A. McBride followed with a paper in which he gave the histories of five cases of migraine with supra-orbital neuralgia and other symptoms, which treatment failed to relieve until some nasal affection had been discovered and cured. In these cases the diagnosis and treatment of the nasal affection was by specialists in rhinology. In one case troublesome rumination disappeared after treatment applied to the nose.

Dr. Beverly Robinson read a paper chiefly devoted to a consideration of hay fever and asthma as reflex symptoms of nasal disease. Such connection had been shown to exist by McKenzie, of Baltimore, Daily, of Pittsburgh, and had been widely confirmed by operations on nasal disease at the hands of numerous rhinologists, the hay fever or asthma disappearing upon the institution of nasal treatment. Dr. Robinson took a middle view on the question whether the sensitive part of the nasal mucous membrane was very limited or widely distributed; and regarding the use of solution of cocaine for the allaying of pain and to reduce the thickened condition of the lining membrane of the nose, he thought that if used for some time the result would be to cause hyperæmia.

The subject was further discussed by Drs. Goodwillie, Baruch, Schweig, and the President.

NEW YORK PATHOLOGICAL SOCIETY.

Stated meeting, February 10, 1886, John A. Wyeth, M. D., president, in the chair.

Chronic Endocarditis with Interstitial Myocarditis as a Result of Partial Occlusion of the Coronary Arteries.

Dr. T. Mitchell Pruden presented the specimen with a brief clinical history, for which he was indebted to Dr. Polk. The specimen was interesting from the fact that it was a good illustration of the pathological condition present, and also because it was one of those cases in which patients suffering from a serious lesion of an important organ get along very well until some intervening condition disturbed the balance, when death was liable to take place from the original disease. This patient had resolving pneumonia when death occurred. There was also Bright's disease of the kidneys.

Dr. W. M. Carpenter asked whether there was atheromatous change in the arteries in other organs, as the kidneys.

Dr. Pruden replied there was not; that the narrowing from atheromatous degeneration was present only in the coronary arteries. Of course it would be impossible to examine all of the arteries of the body with regard to this condition.

Dr. Carpenter asked the question, because recently there had been considerable discussion regarding the connection between chronic diffuse nephritis and general fibroid degeneration of the arteries.

Dr. Carpenter had in a number of cases found no evidence of general fibroid degeneration of the arteries in chronic Bright's disease. In other cases it was present.

Drs. Pruden and Waldstein concurred in this statement.

Acute Primary Suppurative Nephritis.

Dr. L. E. Holt presented the heart and kidneys of a child dead at the seventh month after suffering three weeks from an acute disease, having previously been strong and healthy. The symptoms at first were obscure, but later there were all of the evidences of meningitis. There also appeared in the urine after the first examination, which was negative, albumen, casts in great abundance, pus and blood. As there was a

family history of tuberculosis, and there were pulmonary signs, Dr. Holt diagnosticated acute general miliary tuberculosis. But the post-mortem examination revealed no tubercles anywhere. There was cerebral congestion, and three ounces of fluid in the ventricles; moderate broncho-pneumonia; and marked acute suppurative nephritis, which was believed to have been primary—a rare condition.

The question as how one could collect the urine of young children being raised, Dr. Holt said he employed a clean sponge placed under the diaper. He thought it was not uncommon for children to cease passing urine for as many as twelve hours, without other cause than perhaps a nervous one.

Dr. Newcomb said with regard to the administration of antipyrine, which was employed in this case, that a friend of his gave two grains to a child under six months, and dangerous symptoms of collapse developed. The child recovered, however.

THE BALTIMORE ACADEMY OF MEDICINE.

Stated meeting held March 16, 1886.

Myopia, with Intense Squint.

Dr. J. J. Chisolm said that myopia, with intense squint, was very rare, the reverse being the rule. He has, however, lately had a case with a most pronounced convergent strabismus and a high degree of myopia. He operated three times in the usual way, and was finally obliged to not only do a tenotomy on the internal rectus muscles, but in addition to stitch the ball to the outer angle of the eye in order to keep it in its straightened position. By this procedure one eye was straightened, but the other still has some squint left. The myopia was congenital, and the high degree of squint was brought about by the very short range of vision.

Pedunculated Growth of the Labium.

Dr. H. P. C. Wilson showed a pedunculated growth of about the size of a hazelnut that he had removed from the labium of a young woman. He takes it to be one of the common moles. He removed it because it gave rise to considerable irritation when she walked. It grew from the skin surface of the labium.

Dr. J. Edwin Michael referred to a case he had reported some time since of a similar growth of about the size of two fists that grew from the left labium majus. It was attached by a pedicle of about the size of the thumb. When in the recumbent posture the growth lay close up between the thighs, but when standing, its elasticity permitted such stretching that by its own weight it hung down almost to the knees. He removed it, and recovery took place without any accident. When he first saw it, it was sloughing at its lower part, probably from a bruise. He has always been at a loss to understand how the woman had become pregnant, with a growth of such a size in such a position.

Dr. Hiram Woods read a paper on

Foreign Bodies in the Orbit,

and related a case in his own practice.

DISCUSSION.

Dr. J. E. Michael has never, in his experience, seen an orbit that he thought could accommodate a piece of wood 3.3 inches long without one end sticking out.

Dr. Woods is unable to find a skull in which the orbit exceeds two inches from before backward. He read the original report of the case referred to, as quoted by Lawson in his book on "Injuries to the Eye Orbit and Lids."

Dr. J. J. Chisolm some years since treated a man who had been stabbed with a penknife through the upper eyelid into the orbit; the lid wound healed kindly, but the orbit wound began to give trouble; he removed later from the socket tissues a piece of knife blade over an inch long. No injury to the ball.

Dr. W. C. Van Bibber had seen some years since a case of tetanus in a man who had the disease as a result of a foreign body in his foot. He had fallen upon it from a distance, and the metal had become imbedded in the tissues. The size was so great that he preferred not to estimate it then, as he did not have the foreign body at the meeting with which to corroborate his statement.

Dr. P. C. Williams saw in one of the Paris hospitals a man who had been shot under the right eye, and the ball came out behind the left ear. He recovered.

Dr. J. J. Chisolm has seen these injuries destroy both sight and hearing, without destroying the brain. He had once removed a splinter of hard wood from a man's cheek. It had remained in this position, just below the eye, for nine years, without giving rise to any trouble whatever.

Dr. Chas. H. Ohr had seen a man in whose flank a ball had entered, splintering the spinous process, and coming out behind the hip-joint on the opposite side.

Dr. J. E. Michael has no doubt of what *has* happened; but certainly, lately—that is,

in the last four or five years—all the gunshot wounds that he has seen, if fired from a pistol of any size, were remarkable for the *direct* course taken by the ball. It may be due to an improvement in the kind of firearms now in use, or in the ammunition, but certainly in his cases the ball has passed straight through all the tissues.

He cited the Garfield case as a result of what may be done with the 38-calibre English bull-dog pistol, the weapon most commonly used.

Dr. C. H. Ohr thinks deflected bullets are usually partly spent, or else are feebly propelled. He does not believe a ball will usually be deflected, if properly propelled and fired at close range.

He had seen a case of a man who held a pistol in his hand, and directed it into his thigh, just above the internal condyle of the femur; the ball passed straight through the joint and came out below the head of the fibula.

Dr. P. C. Williams thinks the angle at which a ball strikes a tissue has much to do with the direction it takes afterward.

Dr. J. J. Chisolm thinks short range will explain the frequency of straight wounds in civil practice.

Dr. J. E. Michael had recently seen a man who had, in attempting suicide, fired four small balls (22-calibre) into his head; none of them penetrated the skull.

(*To be continued.*)

Editorial Department.

Periscope.

The Influence of Kairin, Thallin, Hydrochinon, Resorcin, and Antipyrin on the Heart and Blood-vessels.

Chemists, for a number of years, have been industriously experimenting, hoping to find a way to produce quinine artificially. The result has been the discovery of a number of substances, some of them belonging to the phenol series of organic compounds, and possessing to an eminent degree the power of reducing hyper-pyrexial temperatures. Of these, kairin, thallin, hydrochinon, resorcin, and antipyrin, have all been found to reduce abnormal temperatures to a greater or less degree, in almost all febrile disorders promptly, though perhaps not permanently. An experimental inquiry into the probable relations of these new antipyretics to the circulatory apparatus has been made by Dr. H. G. Beyer, and the results, which he gives in an elaborate article on the subject in the April number of *The American Journal of the Medical Sciences*, justify an attempt to solve the problem.

The experiments have been arranged into two groups:

1. Experiments on the work done by the heart when isolated from the central nervous system.

2. Experiments on the blood-vessels: on the flow through the vessels of animals the brains and spinal cords of which had been destroyed; on the lingual vessels of curarized frogs.

In addition to this, a short account of the influence of these drugs upon the corpuscular elements of the blood and the coagulation of blood is given.

Dr. Beyer's experiments show that kairin reduces temperature, both by diminishing heat production and by increasing heat radiation. The distinctive influence it exerts on the red blood-corpuscles, however, and the weakening effect upon the heart, render its employment objectionable and dangerous.

Thallin, like kairin, reduces temperature by diminishing heat production, and by increasing heat radiation; as an antipyretic it is less dangerous, but no less objectionable, than kairin, for while its effect upon the ventricle of the heart is less depressing than that of kairin, its influence upon the blood-corpuscles is sufficient to condemn it.

The action of hydrochinon is similar to that of kairin and thallin. Resorcin reduces the temperature by increasing heat radiation by the dilatation it produces in the capillaries and veins, especially the latter.

Antipyrin reduces temperature purely by increasing heat radiation, owing to its extensively dilating the veins and capillaries; but what stamps it as an excellent antipyretic is that, besides dilating the veins, it also has a tonic influence on the heart and slightly increases arterial pressure, or, at any rate, does not cause a diminution of the same. It has, moreover, no injurious influence on the blood or the muscular tissues, and strengthens the auricles.

The objection to the employment of kairin and thallin as antipyretics arises from the fact that they cause heart paralysis, espe-

cially affecting the auricles, in doses only slightly larger than are sufficient to produce a lowering of the temperature. But this objection becomes an absolute danger when we take into account the destructive influence upon the blood-corpuscles and tissues generally.

Hydrochinon and resorcin, although not exerting the same weakening and directly paralyzing influence upon the ventricle of the heart which is peculiar to kairin and thallin, both paralyze the venous side of the heart, viz., the auricles, and greatly lower the tone of the walls of the veins. The extra amount of blood, therefore, which is driven into the veins through the increased action of the ventricle, is only with great difficulty returned to the ventricle, and here the danger is not so much from failure in the power of the ventricle, as in the case of kairin and thallin, as from the danger of *bleeding the animal to death into its own veins.* The intense visceral and especially pulmonary congestion found post-mortem by Dujardin-Beaumetz and others, in animals killed by resorcin, seems to confirm this view of the matter.

Antipyrin, though largely dilating the veins, increases the power of contraction of both auricles and ventricle, and has no injurious influence upon the blood nor the muscular tissues, and therefore possesses, indeed, all the good qualities of a perfect antipyretic.

Lactic Acid as a Destroyer of Pathogenic Tissues.

The *Annals of Surgery* says:

Since Mosetig-Moorhof's favorable results with this agent (*Centbl. f. Chirg.*, 1885, No. 12,) various other observers have made use of it, in lupus, superficial epithelioma, papillomatous growths, fungous processes, scrofular ulcerations, laryngeal phthisis, etc. Its advocates claim that it is not a true caustic, but selects diseased and spares healthy ti ssue. Wherever its application is practicable, it is consequently to be preferred to curetting.

The acid is a syrupy liquid miscible with water. Though not considered necessary by some, its action may be confined by covering surrounding parts with plasters, collodium, or traumaticin; fats are an impediment. It is applied on linen, felt, or the like, either pure or reduced with water, or mixed as a paste with pure pulverized silicic acid. It may be applied with a brush, but does not then act as rapidly. It is further recommended to bind it on with rubber, paper, or other confining material. It causes considerable pain for a few hours (Bum says 1-3) and is usually removed in twenty-four or less.

Joseph (*Deut. Med. Woch.*, 1885, No. 43,) cured a leucoplakia buccalis with 80 per cent. diluted lactic acid. Schnitzler reported at the September Naturforscher-Versammlung his experience with it—not very favorable—in tuberculosis of the larynx. Krause, of Berlin, has also used it in this affection, and Jellinek (*Wien. Med. Wochenschrift*, 1885, No. 46), in Schrötter's clinic, has for some months given it a more thorough trial. For this purpose he prefers a 20 to 80 per cent. solution. The healthy mucous membrane is but slightly affected, while infiltrated portions are slowly destroyed. The more succulent the infiltration, the more vigorous the action; œdematous parts shrink in three or four days, and troubles in deglutition are rapidly relieved. Most favorably affected were small ulcerations, especially on the vocal cords; larger sores were only prevented from further growth. In ulcerous, granular and hypertrophic pharyngitis he had good results. In nasal troubles simple brushing does not suffice; longer contact is necessary. J. believes that in laryngeal phthisis by daily applications more can be accomplished with this than with any other remedy, and that in its earlier stages it can thus be cured.

Bum (*Wien. Med. Wochenschrift*, 1885, No. 47) has for several months been employing it in fungous, *i. e.*, tubercular disease of soft parts—skin, subcutaneous tissue, lymphatic glands—in dispensary practice. The unhealthy granulations are reduced to an easily reducible pulp; the walls of the cavity do not bleed; after two or three applications, with intermediary pauses of two days, a permanent dressing of iodoform gauze is used, abundant healthy granulations develop, and a smooth, soft scar results. Lactic acid will attack healthy as well as unhealthy epidermis, but in the subdermal tissues it seeks out fungous nests and destroys them. B. gives short histories of nineteen cases in patients from 1 to 52 years of age. There were eight males and eleven females; eight ulcers, seven fungous and four fistulous. The average number of acid dressings was three, and the average time of cure twenty-five days, or, deducting one who removed dressings, but nineteen and eight-tenths days. No failures, and up to date, six weeks to five months later, no relapse.

Finally, Mosetig has returned to the subject again (*Wien. Med. Wochenschrift*, 1885, No. 48), with the demonstration of good results in a large facial epithelioma in a man æt. 55, and an ulcus rodens on the face in a

women æt. 60. In the former he had made twenty-six applications in a month, and in the latter he had made twenty already. In caries he finds it excellent, good demarcation being produced, and there being less liability to relapse than after curetting. He has tried injections of the acid, ½ to 1 gram. of a 50 to 70 per cent. solution. Whether relapses may yet occur, he, of course, cannot say.

A Modification of Fehling's Solution for Testing for, and Estimating Sugar in Urine.

Dr. F. Cresswell thus writes in a foreign exchange:

I have always found that the chief inconvenience in using Fehling's solution for estimating sugar was that it would not keep for above a few weeks at the outside, and in hot weather it frequently became untrustworthy in a much shorter time. This trouble is owing to the readiness with which the sodium and potassium tartrate undergoes decomposition. I have therefore tried to dispense with the use of this salt, and I think have succeeded thoroughly in the following manner: After trying several organic substances which were not prone to decomposition in an alkaline solution, I have found that glycerine answers best. It completely prevents the precipitation of copper sulphate by caustic potash or soda, and the solution will keep for an indefinite time in an open vessel—in fact, until the caustic alkali becomes converted into carbonate, and in a stoppered bottle seems quite permanent.

I find that grape-sugar reduces somewhat less copper from the glycerine solution than from the tartrate solution, and that uric acid will scarcely attack it, whereas it was one of the chief causes of fallacy in Fehling's test.

The best method of preparing the solution is as follows: Take about 35 grammes of copper sulphate, and dissolve it in 200 cubic centimetres of glycerine and 100 cubic centimetres of water; then add 80 grammes of sodium hydrate dissolved in 400 cubic centimetres of water, and boil the whole for fifteen minutes. This is necessary, as all the specimens of glycerine which I have met with contain a small quantity of some substance capable, at a boiling heat, of reducing an alkaline solution of copper. After boiling, the solution is made up to 1 litre with distilled water, and allowed to stand until it is clear. It must be standarized by a solution of grape-sugar of known strength for accurate determination, and is sure, if made as above, to require diluting. If it only be required for rough clinical purposes, the above quantities may be diluted to 1250 cubic centimetres; 10 cubic centimetres will then be approximately equal to 5 centigrammes of sugar.

The process is carried on in exactly the same way as the well-known method of Fehling; 10 cubic centimetres of the copper solution are mixed with 50 cubic centimetres of water, and boiled in a small flask, and the solution of glucose (which should not contain more than one per cent.) is slowly added from a burette, the contents of the flask being kept steadily boiling until the original blue color of the solution has entirely disappeared; the quantity of the solution used must then have contained 5 centigrammes of sugar. Diabetic urine usually requires diluting to one-fifth or one-tenth, in order to reduce the sugar below one per cent. For example, 10 cubic centimetres of a diabetic urine were dilated to 100 cubic centimetres, and transferred to a burette; 10 cubic centimetres of the copper solution require for complete decolorization 26 cubic centimetres of this diluted urine; 2.6 cubic centimetres of the original urine, therefore, contain 5 centigrammes of sugar, or 100 cubic centimetres would contain 1.92 grammes, or 1 ounce (437.5 grains) would contain 8.4 grains of sugar. In the quantitative examination of urine for sugar a few drops of the copper solution are mixed with about 5 cubic centimetres of water and boiled, about ten drops of urine are added, when, if sugar be present, on again boiling for a few seconds, the characteristic brick-red hydrated suboxide of copper will fall.

I hope the above will prove especially useful to country practitioners, who seldom require to test for or estimate sugar, and who, when they do, by using the above solution, will escape the annoyance of finding their testing solution decomposed and useless. I have had some of the above solution in an ill-stoppered bottle for between four and five years, without any signs of decomposition.

Typhoid Fever; Death Eight Months after from Ulcers of the Intestines and Diseased Kidneys.

Mr. Lockwood thus writes in the *Medical Press*, March 17, 1886:

Ellen C., æt. 22, was admitted into the Sheffield Public Hospital on October 22, 1885, under the care of Dr. Thomas, to whom I am indebted for permission to relate the following notes of the above case:

On admittance, she said that she had been in the infirmary at the Firvale Workhouse six months ago with typhoid fever, and Mr.

Kilham has kindly furnished me with the particulars of her illness there, together with the temperature chart.

"Was admitted into the Union Infirmary on May 20, very anæmic, not much purging during the first few days, but afterwards had five or six motions per diem, of the usual typhoid character. About the end of June she had severe pain in the lower part of the abdomen, swelling and some hardness and some dullness over the left ovary and broad ligament, very tender on pressure, and due (Mr. Kilham thought) to inflammation of the above structures. With opiates and fomentations the pain and swelling subsided in a few days. There did not seem to be any tumor internally, but she was not examined per vaginam. After all her pain and diarrhœa had disappeared, she was kept in bed for a good month, because her temperature was high. She said that she felt all right and wanted to get up. On July 25, she was put on the citrate of iron and quinine, and became stronger every day, and was discharged at her own request September 13, after four months' residence. Her temperature was invariably high at night. She had not been unwell whilst an in-patient, and had no cough."

She was thus admitted under Dr. Thomas one month after leaving the workhouse infirmary, having tried to resume her work, but failed, and the old pain returned in the abdomen, she lost flesh and had constant diarrhœa, with sickness and pain in the back.

On admission, her condition was as follows: Very pale and anæmic, much emaciated, diarrhœa, abdomen tympanitic all over, with great tenderness over both iliac regions, and a swelling in the left one and gurgling in the right. The case was diagnosed as either relapse of the typhoid with peritonitis, or else tubercular peritonitis, but she had no lung sickness.

During the whole of her stay in the hospital her symptoms remained fairly consistent. She lost flesh, had diarrhœa of an intermittent character, the stools at times stained with blood, vomiting especially during the latter part of her life. She sank gradually, and died on December 28th, two months after her admission, and eight months from the commencement of her illness. She was examined per vaginam, and the uterus was found to be firmly fixed, hot and tender to the touch. There was albumen in the urine, but not to a large amount, and the heart and lungs were normal.

Post-mortem was made twenty-four hours after death. On opening the abdomen, the omentum was scanty, and the walls of the intestines extremely thin and almost through in one or two places. All the pelvic organs were firmly adherent, and could not be separated. The right ovary had apparently undergone cystic degeneration, as had also the left one. On opening out the ileum, seven or eight ulcers were found, specimens of which are shown, extending from the cæcum up the ileum for about two feet, but there were none elsewhere.

Kidneys.—The left kidney was of great size and had the appearance of a large white kidney. The right kidney was completely riddled with cysts, and its supra-renal capsule was of great size, very like the appearance of those bodies in Addison's disease. All the other structures were normal.

Remarks on Colloid Degeneration of the Skin.

Dr. Robert Liveing thus writes in the *Brit. Med. Jour.*, March 27:

Three cases of a rare degeneration of the skin have come under my observation during the last few years, to which I desire to call the attention of those who are interested in dermatology. Unfortunately, all three cases occurred in private practice; and I have been unable to exhibit them, or even to make a microscopic examination; therefore all my remarks will be simply clinical.

I will preface these remarks by saying that a similar disease or degeneration has been referred to by Wagner, under the name colloid milium, and by Besnier as "colloid degeneration of the skin." Duhring says "the disease is characterized by numerous disseminated, small, pin-head sized, discrete, rounded, flat or slightly raised lesions, of a pale or bright lemon color. They are shining and translucent, and have the appearance of being yellowish vesicles. Their appearance, however, is deceptive, for they are of firm or solid consistence. When pricked with a needle, or opened sufficiently deep to cause bleeding, a whitish, or yellowish, transparent gelatinous substance may be expressed." He also says that it resembles xanthoma, but the lesions differ in being bright and translucent. With this latter remark, I entirely agree. In each of the three cases that I have seen, the first glance led me to believe that I had before me a case of xanthoma, and suggested to me the name colloid xanthoma. A careful examination, however, satisfied me that the disease was not xanthoma, or at all events that, if the little growths were originally

xanthomatous, they had undergone, and were undergoing, remarkable changes from their original condition, and quite unlike those usually seen in xanthoma.

The first case I met with was in a young woman; of this case, I lost sight. The second was in a man; the disease attacked his face and neck, and ran its course in about a year; he at last quite recovered. The third instance was in a girl of about 16, in whom the face, neck, and arms were attacked. The following brief description taken from my notes of one of the cases, will apply pretty nearly to the other two. The little growths are scattered about the face, neck, and upper arms, and many of them are undergoing metamorphosis; there are, however, one or two very perfect ones on the back of the neck. They consist of small, slightly raised, yellowish tumors, varying in size from a large pin's head to a split-pea, somewhat flat, of solid or semi-solid structure, but from being translucent, they look as if they contained fluid; minute vessels are seen round the margin of some of the larger ones; the appearance of these reminds one of the rodent ulcer in its earliest stage, though the resemblance is in appearance only. These little tumors undergo change by the formation of a central depression, so that many are umbilicated, the depression gradually becoming a shallow, crater-like excavation; and, lastly, they inflame, scab, and dry up, leaving a mark, but not a defined scar. The changes which they undergo remind one of those seen in molluscum contagiosum, but the general appearance is not very like that disease, and could not be mistaken for it.

It would be interesting to determine the two following points with regard to the disease: (1) where, and under what circumstances, the disease originates, whether from previously healthy skin; or (2) whether the degeneration may not occur in more than one disease of the skin, such as, for example, milium, xanthoma, and molluscum contagiosum.

Pure Terebene in the Treatment of Winter-cough.

Dr. C. W. Suckling says in the *Brit. Med. Jour.*:

Upon seeing in the *British Medical Journal* for December 12, 1885, Dr. Murrell's eulogistic account of the action of pure terebene in winter-cough, under which name, I presume, he includes all cases of chronic bronchitis and emphysema, also cases of chronic phthisis, but not those cases depending upon heart disease, I determined to give the drug a trial in the Birmingham Workhouse Infirmary, where a great number of such cases are met with during the winter months. I had for some years previously frequently ordered terebene inhalations for the relief of urgent dyspnœa in these cases, but had never administered the drug internally. I accordingly prescribed pure terebene, obtained from Messrs. Southall & Co., the well-known Birmingham chemists, in 100 cases, giving five drops every four hours, increasing the dose to ten drops in a day or two, with the following results:

Of the 100 cases, 94 were cases of chronic bronchitis, and 6 of chronic phthisis. Of the cases of chronic bronchitis, 68 were relieved, and 4 of the cases of phthisis; that is 72 per cent. of all the cases were benefited. Several of the cases were "greatly" relieved. Twenty-eight patients were not relieved; 11 complained of nausea, 11 of headache, 10 of thirst, 2 of vertigo, 2 were purged, 1 complained of a burning sensation at the stomach, and 1 that he was always passing his urine. The symptom most constantly relieved was dyspnœa. The 72 patients benefited all said that the medicine eased their breathing, but many asked for medicine in addition to ease the cough.

I compared the above results with those obtained previously by our routine method of treatment, which consists in prescribing a mixture of ammonia and senega (℞. Ammoniæ carbonatis, gr. iij.; tincturæ scillæ, ♏xv.; tincturæ camphoræ co., ♏xv.; infusum senegæ, ad ℥j.), with the occasional addition of a few grains of iodide of potassium if expectoration were difficult, and of a small quantity of lobelia if dyspnœa were marked, many cases also being given cod-liver oil, the latter being, in my opinion, one of the most useful of all drugs in the treatment of chronic bronchitis. I collected the prescription papers of 100 cases that had been treated during the last few weeks before I commenced the terebene treatment. Of the 100 cases, 28 were discharged well, the chest being perfectly clear; 68 were discharged relieved, and 4 left the infirmary unrelieved. None of them complained of any ill-effects of the remedies used.

The great majority of the cases treated in the infirmary were old people, who had suffered from bronchitis for years. Of course, the mere admission, from their wretched homes, of these patients, into warm wards, with good food and nursing, will account for a great deal of the relief given, but this holds good in the case of the terebene as with the other drugs given.

I feel obliged to conclude, from my experience with terebene—

1. That it greatly relieves the dyspnœa of chronic bronchitis.

2. That it is very variable in its action, the same specimen causing good results in some, bad symptoms in other patients.

3. That it is by no means a specific for chronic bronchitis.

A Note on Lewinin, the New Local Anæsthetic.

Dr. N. A. Randolph thus writes in the *Med. News*:

In the editorial columns of the *Med. News* of February 13, 1886, there is given a brief account of the physiological properties of a semi-fluid resin obtained from the root of piper methysticum.

In the method employed in obtaining it (extraction by petroleum-ether) two resinous bodies are obtained. the resin of lesser density only being efficient. To this body Lewin, its discover, applies in his original communication the rather cumbrous title of "Alpha Kawa Resin," for which I have ventured to substitute the name Lewinin, as above.

Although I have not been able to obtain, in my experiments with the extract in question, results as marked as those presented by Lewin, several points of clinical interest have arisen, which will, I think, be of interest.

When the semi-fluid Lewinin is placed upon the tongue, there is a momentary burning sensation with increased salivary secretion, followed by a local numbness, which, while extremely superficial, is recognizable for more than an hour. Some pallor of the mucous membrane at the point of application is noticeable. I have several times swallowed about five grains of the extract thus placed upon my tongue, without appprecíable results other than those noted.

Lewinin is too painfully irritating to apply in practice to the human conjunctiva, but it is my belief that, by the previous application of cocaine, the Lewinin in solution could be instilled into the conjunctival sac, and produce its characteristic effect of prolonged local anæsthesia before the more temporary effect of the former drug had passed off.

The extract will probably be of service in dental practice, as its application certainly mitigates the discomfort of operations on the teeth of those suffering from sensitive dentine.

The most marked practical benefit, however, to be expected from the use of the drug is in cases where only a relatively superficial anæsthesia is desirable. Thus, as would have been expected, the drug is of value in rhinological practice.

Dr. Harrison Allen, to whom I handed a fifty per cent. alcoholic solution of Lewinin, kindly reports that, in practice, he has found a number of cases of nasal trouble in which the drug could not only be availably substituted for cocaine, but in which its action was more satisfactory.

The extract just discussed was prepared for me something over a month ago by Mr. Llewellyn, of this city, and was, I believe, the first specimen of the drug produced in this country.

Dislocations of the Shoulder-Joint.

Dr. Thomas H. Manley writes to the *Medical Record* that his experience during the past year with luxations of the shoulder has led him to regard the accident as a much more serious one than is generally supposed. It is impossible to tell from inspection, immediately after dislocation has occurred, how easy or how difficult its reduction will be; and after repeated attempts at reposition have been made without success, another effort, perhaps by another surgeon, may be followed by the desired result. He says that of ten cases seen by him in the past year, eight were subglenoid, and were easily reduced, while 2, which were subcoracoid, were absolutely irreducible. In the successful cases ether was used only once, its administration being required on account of the severe pain. In one of the irreducible cases, occurring in an epileptic, the effect of ether was to cause a tetanic rigidity of the muscles, which, at times, became so general and so marked as to interfere with respiration. The writer believes that ether is seldom required, despite the generally accepted opinion to the contrary. Its principal value is to relieve pain, but it is questionable whether the relaxed state of the muscles which it induces is of any real value to the surgeon in the majority of cases. Dr. Manly sums up with the following conclusions: 1. The surgeon should not attempt the reduction of a dislocated shoulder without the aid of an experienced assistant. 2. Without great caution in manipulation and care not to use violence, he may very seriously injure the joint by lacerating the tissues, or fracturing the bone. 3. With the best directed efforts, some dislocations of the shoulder cannot be reduced.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

RESORCIN IN SKIN DISEASES.

Resorcin has recently been repeatedly employed in acute and chronic diseases of the skin. Dr. M. Ihle, in Leipsic, has specially investigated the effect of this drug in various chronic exanthemata, and from his report, published in the *Monatsch. f. pr. Dermat.*, 12, 1886, we extract the following results of his observations:

Though an excellent remedy in some skin affections, resorcin, in Ihle's opinion, must be cautiously employed. It purifies wounds, ulcers, etc., causes their pains to disappear and diminishes rapidly any existing lymphangitis or lymphadenitis. This can easily be explained. The lymphatic vessels and the glands in all these swell in consequence of an inflammatory condition due to the absorption of the infectious material that has given rise to the ulcer, etc. As resorcin is a reliable disinfectant, by destroying the germs of the virus it soon puts an end to any inflammation caused by the latter. In acute exanthemata, resorcin mostly is too irritating; in chronic skin diseases it is far better, but must be omitted as soon as the degenerated and thickened epidermis has become dry and dropped off. Especially good is the effect of this remedy in herpes tonsurans and in sycosis parasitica; in the latter disease it even causes the falling out of the diseased hair, so that the latter need not to be pulled out. Instead of the usual fatty ointments, I. prefers the application of a porous paste, as follows:

℞. Resorcini puriss., 10.0.
Ungt. paraffini,
Zinci oxydat.,
Amyli, āā 25.0.
M. f. pasta.

Whenever, for some cause, the quantity of the resorcin has to be increased, less starch and zinc must be used to preserve the pliability of the paste. As soon as all formation of pus has ceased, it is necessary only twice to thrice a week to apply the paste as thickly as possible with a camel's-hair brush, and to cover it with cotton-wadding. Usually the treatment is commenced with ten per cent. of resorcin, which is gradually increased to twenty-five and even up to fifty and eighty per cent. With the diminution of the inflammation, this percentage of resorcin is in the same ratio decreased. If the cure seems established, the patient should still continue to apply a three per cent. paste, first daily, and later two to three times a week. He may then, also, recommence to shave himself, while during the time of treat-

ment the hair should be cut only with scissors.

Just as certain as in this disease is the effect of resorcin in other infectious diseases, as in pityriasis versicolor and eczema marginatum. In alopecia areata and that form of seborrhœa which is accompanied by falling out of the hair (seborrhœa cum defluvio capillorum), the falling out of the hair and the intolerable itching may at once be stopped by the daily application to the diseased skin of a piece of flannel over which the following paste has been spread:

℞.	Resorcin. puri,	5.0—10.0.
	Ol. ricini,	45.0.
	Spirit. vini.	150.0.
	Bals. Peruvian,	0.5. M. S.

Pointed condylomata may be rapidly removed by the daily application of a resorcin salve containing 50 to 80 per cent. of the drug. They drop off painlessly, and broad ones too, generally with remarkable rapidity, but care must be taken to protect the neighboring healthy tissues by layers of cotton-wadding.

The only objection to resorcin, especially when it has to be used for a long time and in considerable quantities, is its high price, three ounces costing the apothecary nearly two dollars. Impure preparations are useless and irritating; but the impurity can be easily recognized, as perfectly pure resorcin has a white color, which at once changes to yellow, when the least adulteration is practiced, or when the action of light and air has decomposed the drug.

HEADACHE IN CHILDREN ATTENDING SCHOOL.

As a rule, any child attending school and complaining occasionally of headache, is at once sent by the conscientious physician to an oculist to determine the condition of the eyes. In the January meeting of the St. Petersburg (Russia) Medical Society, Prof. Bystrow, of St. Petersburg, mentioned a number of observations which he had made in a girls' normal school, and on several other children attending private schools. In the normal school were 375 girls, and of these 27 per cent. suffered with headache. Of 7478 girls and boys attending school and observed during a period of five years, 868, *i. e.*, 11.6 per cent., were found to be affected with headache. The older the children the more frequent and violent the pain in the head, so that of the children between 14 and 18 years old, from 28 to 40 per cent. were found to complain of headache. B. explains this occurrence by mental overstrain, to which the children in modern schools are exposed, for he met with this ailment not only in children visiting public schools, but also in those who, surrounded by the most favorable hygienic conditions, received private instructions at their homes.

B., for this reason, expresses the view that in every school-board a physician should be a member to give his advice as an expert. His remarks gave rise to an animated discussion. Prof. Polotebnau thought that the miserable hygienic conditions, as they now exist in schools, were mainly responsible for many a disturbance of the health of the children attending these schools; while Dr. Akulow believed that in most cases anomalies of refraction were the primary cause for the headache.

The hygienic conditions in our public schools are doubtless far superior to those of Russia, but in the practice of the writer of these lines many cases in the children attending the public schools and suffering with headache, showed no abatement of the pain whatever after the children had been supplied by an expert with the proper glasses, while diminished studies and greatly increased out-door exercise had the desired effect. We believe that in our schools the memory of the children is taxed too early and too persistently.

Notes and Comments.

Dentition in Infantile Pathology.

That children specially suffer during the critical period of dentition has long been recognized as a fact, but the question has never been determined what the influence is that causes these disturbances. The article is, therefore, interesting which Ségournet has published on this subject in the *Revue Mens. des Malad. de l'Enfance*, September, 1885.

S. carefully watched 113 children during their period of dentition; forty-seven evinced no general disturbance (S. did not consider local affections of the mouth); five suffered from bronchitis; fifteen times convulsions occurred, partly followed by nervous, cerebral, meningitis, or spinal symptoms; forty-one were affected with gastro-intestinal maladies, and five had skin diseases. *All the accidents occurring during the period of teething mostly are a product of which dentition generally is only a factor.* S. compares dentition with other transient functions—gravidity and menstruation—which, according to the peculiarities of the organism, exert a varying in-

fluence upon it. He proves by figures the favorable influence which the fact of the children being nursed by their own mother has upon dentition, and believes that the first necessary condition for a normal dentition, unaccompanied by any morbid disturbance, is that of the child receiving its first and only nourishment from the breast of its mother. A peculiar urine is often met with during the period of dentition in children. It is a milky febrile urine of acid reaction, clearing up under boiling, and free from sugar, albumen, and fat. Eclampsia usually occurred in children fed by the bottle, or otherwise unsuitably nourished, or in such whose parents were nervous, or who had hysterical mothers, or who were rhachitic or very stout.

Skin diseases happened only in children in whom a hereditary influence of that kind could be proven to exist, while affections of the respiratory organs are explained by the fact that the irritation of dentition induces vaso-motor disturbances, which give rise to these catarrhal conditions, while in cases of gastro-intestinal symptoms some predisposing or directly existing cause besides the dentition was invariably present.

A complete knowledge of the family history and of the individual tendencies of the child will enable us, according to S., to prevent these complications during dentition, though all our endeavors will mostly be in vain, if we cannot insist upon the child's being supplied with nutrition by its natural food—the milk of the mother, or in case the physical condition of the latter is not one of the best, that of a healthy wet-nurse.

Urethral Fever, with a Record of Three Fatal Cases.

Mr. F. S. Edwards, who writes on this subject in a foreign exchange, believes that this fever is nearly always caused by some disturbance of the urethra, and notably of its fixed part. The mere emptying of a distended bladder is insufficient to give rise to this fever; because it is not met with, after relief of the bladder either by rectal or by suprapubic puncture. Statistics indicate that, contrary to Sir Andrew Clark's opinion, the tendency to urethral fever is not lessened by the use of anæsthetics in urethral operations. During the past three years at St. Peter's Hospital, urethral fever, generally the acute transient form, followed in exactly fifty per cent. of all strictures operated upon under anæsthetics. In fifty-nine cases without anæsthetics, rigors followed in only eighteen. As regarded internal urethrotomy, anæsthetics were given forty-seven times, followed in twenty cases by rigors. This operation was also performed forty-seven times without an anæsthetic, rigors occurring in only nineteen cases. Three fatal cases were related; in the first, there was a sloughy, false passage, and commencing endocarditis. In the second, hemiplegia and death followed the passage of a bougie in an old man strictured for nine years. In the third, internal urethrotomy had been performed, and death from septic poisoning occurred on the fifteenth day. In conclusion, the author remarks that he has never known rigors follow division of the meatus or of anterior strictures, where the deep urethra has been left untouched. Urethral fever might be due either to local irritation, or to absorption, and probably, in some cases, to both combined. In certain stricture cases, the mere passage of a bougie was followed by rigors, which did not recur after the division of the stricture. If, in these cases, the rigors and rise of temperature were due to absorption, it was hardly possible to explain the non-recurrence of these symptoms when a wound of the urethra had been subsequently inflicted, and the conditions made eminently favorable for absorption. Such cases of fever were probably of neurotic origin. The occurrence of urethral fever might be avoided by puncturing the bladder through the rectum before performing internal urethrotomy, in order to divert, for a time, the urinary stream, and thus to keep the urine from contact with the wound, for it was by this contact that urethral fever was excited.

Thallin.

Dr. Janssen, in an article in the *Weekblad van het Nederlandsch Tijdschrift voor Geneeskunde*, mentions that he has had a favorable opportunity, in the military hospital at Helder, for testing the value of thallin. He used exclusively sulphate of thallin, dissolved in alcohol and water. This solution possesses an aromatic taste and smell, and is perfectly harmless, both when inhaled and when taken internally. It has a strong antibacteric action. The average dose given was one gramme. Dr. Janssen observed seventeen cases of malarial fever; in sixteen the thallin was of less use than quinine, since it produced no permanent effect on the disease, only serving to prevent or shorten attacks; but, when its use was discontinued, the fever returned. The indications for the use of thallin Dr. Janssen does not consider

to be numerous. In regard to antipyretic treatment, thallin should be preferred in those cases only where the temperature attains such a height as to endanger life; and, even then, he is of opinion that cold baths are better. If, however, circumstances exclude the use of cold baths, thallin is of great service, acting quickly and producing no dangerous symptoms. There is no injurious effect on the kidneys. Thallin is preferable to kairin, which produces numerous complications and unpleasant results, yet gives an extremely short period of apyrexia. It is also preferable to antipyrin, which must be used in large quantities, and, when used as an injection, is apt to produce vomiting. Dr. Janssen states that he has seen a scarlatinal patient, after an antipyrin injection, seized with violent collapse; and that another patient, who had taken 5 grammes of antipyrin, exhibited symptoms of cardiac adynamia. Antipyrin is, however, superior to thallin in the duration of the apyrexia produced. Dr. Janssen has found thallin of great service in phthisis, as very small doses control the fever.

Etiology of Scrofula in Early Childhood.

Dr. J. Comby (*Woch. Gen. de Med.*, October, 1885,) has made a special study of scrofula in early childhood. He observed the dyscrasia in 100 cases, 25 times in children under two years of age. There appeared to be no difference between girls and boys, and lymphatic temperament, instead of being the cause of the disease, was simply its first manifestation. The malady seemed to be especially frequent in the children of parents who had been formerly living in the country, and later moved into a large city. Malnutrition forms the main factor in the etiology of scrofula, for not only does it give rise to the disease in those by nature disposed to it, but it will develop even that very disposition. C. reports in his article a large number of cases in illustration of the facts mentioned.

Of the infectious diseases which create a tendency to scrofula or directly produce it, measles seem to be the most prolific. Next to measles and in the order enumerated come variola, typhoid, whooping-cough, and erysipelas. Regarding the question whether scrofula is contagious or not, C. contends that there is not a single case on record that proves such a theory. Inoculations with the virus of scrofula taken from suppurative scrofulous glands have partly been successful, partly not. It is difficult to demonstrate the presence of bacilli, and often when inoculation had been successful no bacteria were to be found.

Concerning treatment C. has nothing new to recommend. The etiological factors in many cases being known, it is the duty of the physician to prevent their occurrence, but here we find a serious obstacle in the fact that the disease attacks mainly the children of those who have not the means to employ the preventive measures most urgently needed.

Pericarditis and Pertussis.

One of the most interesting articles that have of late appeared in foreign journals, is one of Prof. Giovanni Racchi (*Arch. di Path. Infant.*, 5, 85). He attended a child suffering from whooping-cough. Soon capillary bronchitis and broncho-pneumonia developed as complications, and became so grave as to cause the death of the infant, four weeks old.

The post-mortem examination revealed not only the lesions above mentioned, but also a purulent pericarditis. As this disease in the manner in which it occurred in the infant happens only in cases of infectious diseases, R. first read the literature on the subject, and found that while whooping-cough is rare in young children, it occurs more frequently during the first few months of life than later in the first year. In cases where death set in, a frequent occurrence during early childhood, tubercular meningitis, peritonitis and pleuritis always accompany the pertussis.

R. thought, therefore, that the infection may first set in from the umbilicus; that whooping-cough was an acute infectious disease resembling miliary tuberculosis; and that the complications, as for instance, the pericarditis, were the direct consequences of the same virus, which in some cases was of a milder, in others of a graver nature, just as the poison of variola may give rise to the same disease, but of varying intensity, in different individuals.

To determine the question, R. took some of the purulent discharge and brushed it over the mucous membrane of rabbits. On the third day in some, on the fourth, fifth, and sixth day in other rabbits, the animal commenced to suffer from sudden attacks of coughing; during the next eight or ten days these seizures became more and more convulsive, and led to attacks of suffocation, and finally the animal died. The post-mortem revealed the same lesions in the pericardium, and in some rabbits also meningitis and pneumonia developed.

The virus taken from these animals in again others also gave rise to convulsive and suffocative attacks of coughing gradually increasing in severity, and with a period of incubation of twelve to fourteen days. Some of the animals, when killed in the third week, showed redness of the pericardium; otherwise the effects were milder but of the same nature.

R.'s investigations form the most important contribution of recent times to our knowledge of the pathology of whooping-cough and of its etiology.

Supernumerary Breasts and Nipples.

In the *Vratch*, No. 47, 1885, Dr. V. G. Favre describes two cases of polymastia and a case of polythelia, which recently have come under his observation in the Zemsky Lying-in Hospital, in Kharkov. One of the patients, an otherwise normally developed, strongly-built peasant, aged 30, had three accessory mammæ, two of which were situated symmetrically along the right and left anterior axillary lines, immediately above the normal glands; their respective dimensions being 11 by 8 and 5 by 5 centimetres. A third accessory gland, of the size of a walnut, was found at the bottom of the right axilla, nearer to the anterior wall of the fossa. Only the largest gland had in its centre a slightly elevated pigmented patch, the remaining being entirely nippleless. On pressure, all three freely yielded milk, which proved, microscopically and chemically, identical with the secretion of the patient's normal glands. In another patient, aged 21, only one accessory mamma of the size of a walnut was present; it was situated in the left axilla, nearer to the anterior axillary line, had no nipple, and secreted normal milk. In a third patient, aged 32, the left mamma had an accessory nipple placed below the normal one, and separated from it by a furrow, about 5 centimetres broad. It was comparatively smaller, but milk was flowing from it in abundance. According to Dr. Favre, his cases are the first of this kind published in Russia. A series of similar cases is mentioned in Dr. R. Neale's *Medical Digest*, Sect. 15–98. A valuable review on the subject, by Dr. Alban Doran, may be found in the *London Medical Record*, August, 1885, page 319.

Sprained Joints.

Before the Harveian Society of London, Mr. Edmund Owen read a paper upon this subject, in which he urged that a sprained joint should be dealt with on the same principles as those which guide the surgeon in his dealings with a fracture at or near the articulation. He advocated rest and compression for the joint, and maintained that if only the part be at once enclosed within a plaster-of-Paris casing, with even compression, effusion will be prevented, and pain allayed. He employed Croft's method of applying the gypsum splints, and urged its adoption in preference to lotions, ice-bags, simple bandaging, and strapping.

Mr. Gant would recognize two classes of sprains; those in which the tendons were affected, and those in which the ligaments only were injured. He related a case in which the extensor tendons had been torn by the foot being doubled under the leg. Passive movements should be employed early, even though pain was caused thereby.

Mr. Kiallmark advocated the use of American plaster, applied at once, instead of evaporating lotions. He would allow passive movement as soon as it was possible without pain.

Mr. Pick thought it difficult to decide when to begin passive motion, but he should generally begin early and persevere, using evaporating lotions at first. He referred to the use of very hot water in recent sprains on the stage.

Mr. Vasey mentioned the successful use of clay mould applied at once round a sprained joint.

Mr. Owen, in reply, observed that he would be guided by the heat or coldness of the joint, and not by pain, in deciding to begin passive motion.

Precautions to be Adopted in the Removal of Residual Urine.

Mr. E. Hurry Fenwick, in this paper, which he read before the West London Medico-Chirurgical Society, laid special stress upon three great causative features:

1. The reflex vaso-motor disturbance of the kidney set up by irritation of the posterior part of the urethra and the vesical nerve-plexuses.

2. The introduction of septic material upon, within, or through the catheter.

3. The injurious effects upon the badly-nourished, thin-walled vascular system of the kidney and bladder on the sudden withdrawal of its accustomed water-pressure counterpoise.

A week's rest in bed, cocainization of the prostate and membranous urethra, aseptic catheterism, the withdrawal, little by little, of the residual urine, and the replacement of

the same by antiseptic solutions, were precautions invariably adopted by Mr. Fenwick in introducing a patient to catheter-life.

Mr. Dunn, in the course of some observations, said that it was not necessary to admit that all rigors following catheterization were the result of septic infection. Some of these could be accounted for by attributing them to the manifestation of latent ague; and perhaps this would explain the rigors which have been regarded as having a neurotic origin. Sir James Paget had shown that an agueish attack might be provoked by an operation, many years after the patient had suffered primarily from the disease.

Compound Fracture of the Patella; Partial Necrosis of one Fragment; Recovery with a Movable Joint.

Mr. G. R. Turner read a paper on this subject before the Harveian Society of London. A fireman, aged 32, was admitted into the Seamen's Hospital on June 1st, 1885, with a compound transverse fracture of the patella. The cavity of the joint was open through a contused wound two inches and a half in width, from which blood was exuding, the patellar fragments being separated by about half an inch to one inch. Thorough cleansing under antiseptic precautions—the limb being fixed on a straight posterior splint, with the wound left open—constituted the first treatment. A blood-clot subsequently was found to be projecting between the fragments, but it was not disturbed. At the end of the sixth week, a small sequestrum came away from the lower fragment. He made an excellent recovery, and was discharged in October, with power to flex the knee nearly to a right angle, the fragments being then separated by about an inch and a quarter and by three quarters of an inch when the limb was extended. In his comments upon the case, the author referred to the slight separation of the fragments in cases of compound fracture, possibly due to the escape of fluid from the joint; to the aseptic course of the case, notwithstanding partial necrosis; and to the question of treatment, in which he gave the preference to the expectant plan, as opposed to wiring.

Case of Tuberculosis of the Skin.

A strumous boy, under treatment in Westminster Hospital, London, with supposed Barbadoes leg, was seen by many visitors to the International Medical Congress, when it met in London, in 1881, and no exception was taken to the diagnosis. The boy had never been beyond the environs of London. He died two years later (aged 18) of a bronchial affection, and a portion of the thickened skin was secured for microscopic examination. There was found to be general hypertrophy of skin; the dermis was thickened from overgrowth of its connective tissue, and the presence of collections of lymphoid cells; in many places there were aggregations of both large and small lymphoid cells, and among them numerous giant-cells, the spheroidal masses thus formed being practically indistinguishable from tubercles, such as were found in the liver and kidney; in the lymphatics, a red staining showed the presence of a small bacillus in great numbers, colonies being also found around the aggregations of lymphoid cells. The case was compared by Dr. Richard Hebb (who reported it), with one reported by the late Dr. Tilbury Fox, where the appearances and history were similar, but the microscopical specimens showed no trace of tubercle.

Great Distension of the Gall-bladder, Treated by Aspiration.

Such cases as the following, which Dr. Irving reported to a recent meeting of the Chester (England) Medical Society, are not common:

The patient, a woman, aged 60, of previous good health, was suddenly seized with severe epigastric pain, gradually spreading to the right hypochondrium, with tenderness. There were slight jaundice and an area of dulness in the region of the gall-bladder, both of which increased. The icterus decreased, but the motions remained pale. A syringe, inserted into the dull area, drew off a light brown fluid. Three days afterwards, there was much bulging, extending over the right side as far as the crest of the ilium. Sixty-two ounces of a yellowish-brown, partly viscid, fluid were withdrawn by an aspirator, with great relief. The fæces still remained pale, but, five days later, there was a copious evacuation per rectum of fluid similar to that aspirated; and, except on one day in which there was a rigor with pyrexia, the patient made a rapid and uninterrupted recovery. The fluid contained a sediment consisting mostly of cholesterine and bile-pigment.

Perforating Ulcer of Foot.

Of late we have several times called attention to this condition, and now we note that Mr. C. Atkin read a paper on this subject before the Sheffield Medical Society, and drew attention to the peculiar deformity of

the toes met with in some instances, a condition originally described by Mr. Bigg and Mr. S. Jones. A man was shown suffering from well marked ataxy, whose toes were not only very much shortened and twisted, but were in parts ankylosed. The existence of this peculiar condition, and the fact that perforating ulcer was often a premonitory symptom of locomotor ataxy, had been strangely overlooked in several recent textbooks on medicine and surgery. The case shown, taken in conjunction with two instances of Charcot's joint disease exhibited last year, proved that perforating ulcer could undergo spontaneous cure, as all three cases presented several scars of previous ulcers. Mr. Atkin considered that this fact ought to make surgeons very chary of advocating such serious operations as removal of bone or amputation of the foot.

Manure-heaps and Diphtheria.

M. Ferraud, in an article published in *Lyon Médical* for March, traces some relation between manure-heaps and epidemics of diphtheria, a disease more frequent in rural districts than in towns and cities. Statistics in Scotland and Prussia show that the rate of mortality from diphtheria is highest in rural districts. In Lyons, the outskirts and surrounding country suffer most. Manure-heaps do not exist in the urban districts, but are plentiful in the suburbs and adjacent country. These heaps consist of various obnoxious and infectious kinds of residue. Klebs, of Zurich, has observed the deadly influence of these manure heaps. He states that diphtheria, on one occasion, appeared on the day following a general street-cleaning. It may safely be concluded that the accumulations of dirt and refuse, known as manure-heaps, are formidable factors in the etiology of diseases among rural populations. M. Ferraud urges that the authorities in agricultural districts should enlighten the peasants on this subject. Manure should be kept in closed wells made of stone and glazed with bitumen, so constructed that all fluid filters away from the solid matter.

Protection from Phthisis.

The Conseil d'Hygiène et de Salubrité of Paris, at a recent meeting, adopted the following decisions: As the sputum of tuberculous patients contains the most active agent of transmission of tuberculosis, it ought not to be thrown on the floor or ground, nor allowed to cling to linen. Patients should use spittoons containing sawdust, which should be emptied at least once a day, and washed with boiling water. The sawdust should be burnt in the fire. These rules should be rigorously observed in schools, workshops, barracks, and hospitals. When a hired room has been inhabited a long time by a phthisical patient, it should be disinfected, more especially if death occur. The room, bed, and bedding should be disinfected by sulphur, according to preceding directions issued by the Conseil. The clothes of phthisical patients should not be used, until they have been washed and disinfected by overheated steam.

Cholesterine in Retina.

To the Sheffield Medical Society, Mr. Snell introduced a boy, aged 10, with cholesterine in the retina. He had been observed to be blind at two years of age. Now there was detached retina, which was much thickened at all parts, but especially so at the nasal side (right eye), where even the naked eye detected the glistening cholesterine plates, which were rendered very distinct with focal illumination or the mirror. The plates were clearly fixed in the retina, which appeared a little wavy at parts. Mr. Snell remarked on the unusual condition, and said that cholesterine had been found in most parts of the eye.

Brass-founder's Ague.

In a foreign exchange Dr. Suckling relates the case of a man who had worked in brass for twenty-six years. The casting-shop was immediately under the room in which the man worked; and whenever any casting was done, the dense fumes given off always made him ill, causing shivering and sweating, very frequently also vomiting, pains about the chest and limbs, and bronchial catarrh. The man had a well marked green line on the teeth, close to the gums, and his hair was of a greenish tint. Dr. Suckling met with the disease very frequently among the out-patients of the Queen's Hospital, and he found that iodide of potassium gave relief.

Rupture of Liver and Kidney.

In the *Brit. Med. Jour.*, March 27, Mr. Haslam relates a case of ruptured liver and right kidney, due to a kick on the abdomen from a horse. The patient, a man aged 29, had no symptoms indicative of a serious lesion until after five days; he was then seized with shock and collapse, his abdomen became distended, and there was suppression of urine.

He died after twenty hours. At the post-mortem examination, about half a pint of blood was found in the peritoneal cavity; this probably came from the damaged under-surface of the liver.

Lead-Tremor.

To the Midland Medical Society Dr. Suckling showed a man, a lapidary, who had suffered for years at times from lead colic. A week before coming to the hospital, he noticed trembling of the hands, which came on somewhat suddenly, and obliged him to give up work. There was marked rhythmical tremor of the hands and forearms on extension, ceasing during rest: also wasting of the thenar muscles, and some weakness of the extensors of the wrist. There was a well marked blue line on the gums.

Correspondence.

On "Emission of Semen as a Means of Diagnosis of Death by Hanging."

Eds. Med. and Surg. Reporter:

With no desire to have my name paraded frequently in the journals, still, it seems to me wrong to allow the statement, or insinuation, that there is an ejaculation of semen in every case of death by hanging, as the literary history of the subject will not bear out such a statement.

Twenty-six years ago I had much to do with the conviction and hanging of a notorious murderer. At that time I was well aware that some authorities spoke of such a discharge as an evidence of death, and I took special pains to investigate the matter.

When death had taken place, as I was the one selected by the sheriff to decide the matter, and before the body had been taken down, I made a careful examination of the urethra and found *not the slightest evidence of any discharge* whatever.

I also examined the parts afterwards, with the same negative result.

Klein (*Jour. de Med. prat. de Hufeland*, 1815,) speaks of this symptom as an evidence of death by hanging thus: "I did not perceive the semi-erect condition of the penis and emission of semen in any of the cases examined."

Beatty says, in *some* cases examined by him he found them wanting. "But as erection and emission are not constantly found in hanged persons, we cannot accord to this phenomenon much value as an indication of death by strangulation, unless accompanied with other characteristic signs, for it has been found in other forms of violent death."

Somewhere I remember to have read (and I regret that I cannot now turn to the authority) that at the hanging of fourteen criminals there was observed a *discharge of urine in five*, and a secretion which, upon careful examination, proved to be *prostatic*, in nine.

In 1839, at Lancaster, in your State, a man was executed, from whose penis there was ejected a fluid, which, after being scientifically examined, proved to be *mucus*.

So that I think we cannot depend upon this seminal discharge as any evidence of death by hanging unless strongly corroborated.

Clyde, N. Y., March 29, 1886.

Treatment of Rhus Poisoning.

Eds. Med. and Surg. Reporter:

I would say in reply to C. E. D., that the treatment which I always adopt, and have never known to fail, is as follows:

℞. Hyposulphite soda, ℥j.
Aquæ distil., ℥viij.
Carbolic acid, ℥iss.
Glycerine, ℥ss. M.

Shake well, and use as a wash three or four times a day, or as often as necessary.

At the same time that I order the wash I prescribe for internal use:

℞. Iodide potassium, ℥ij.
Aquæ distil., ℥vij.
Syrup, ℥j. M.

Sig.—Dose, a tablespoonful four times a day (after eating and at bedtime).

I consider the internal use of the iodide of potassium of great benefit in the treatment of rhus poisoning, and these prescriptions usually promptly cure my patients without the necessity of repeating them. It is said that the rhus owes its poisonous properties to an acid which it contains, and this external and internal alkaline treatment neutralizes that acid, according to my experience.

Neuralgia Cured with Cocaine.

Eds. Med. and Surg. Reporter:

During September, 1885, Mr. Y——, a commercial traveler, came to my office suffering with neuralgia affecting the nerves supplying the temporal and orbital regions. He informed me that he had been subject to attacks of it more or less frequently for twenty years, and for the last few years he

had hardly known what it was to be free from pain, which was often so intense that he was obliged to resort to the inhalation of chloroform for relief. As he was at this time suffering intensely, I suggested the use of cocaine hypodermically for the purpose of rendering temporary relief. To this he readily assented, and two-thirds of a grain was injected midway between the external canthus and the ear on the affected side.

Relief was obtained in a few minutes, and up to this time he has never had a symptom of the old trouble.

I may add that his profound gratitude for deliverance from this life of torture prompted him, in addition to paying the usual office fee, to send me an *eighty-five cent keg of mackerel.* "Such are the rewards of a noble profession." C. S. McClain, M. D.

Marionville, Mo., March 23d, 1886.

News and Miscellany.

London Dust.

Mr. Millar, the vestry clerk to St. George the Martyr, Southwark, has proposed to Sir Robert Rawlinson a comprehensive scheme for dealing with the dust and refuse of the metropolis. His suggestion is to reclaim the useless land from Tilbury to Southbend by removing to it all the refuse of London. The government for this purpose would have to engage wharves along the river which would be used as shoots by the various vestries and district boards, whence the dust would be conveyed to its destination by small tugs and barges. The cost of conveyance to Tilbury he proposes should be paid by a metropolitan rate, and the cost of reclaiming the land by the government. Mr. Millar's scheme will certainly commend itself to these who regard this subject from the public health point of view, but it could not be carried out without interference with certain industries. Brickmakers would argue that the present system which is carried on in London dust-yards is necessary for the purpose of enabling them to manufacture bricks for the growth of London. Farmers have learned to depend upon London road-sweepings and "soft core" for manure; and last, but not least, contractors have learned to make sufficient profits out of London dust to make their influence felt by local authorities. But this industry is less remunerative than formerly, and as a result there is often a tendency on the part of the contractor to leave the dust in dust-bins rather than devote it to the uses we have indicated. Hence, there has for some time been a growing feeling that some radical change was necessary in the method of dealing with the waste material of this large city. Efforts have been made by more than one metropolitan medical officer of health to bring to the notice of his sanitary authority the advantages of burning house refuse in some such manner as that practiced in the north of England. Vestries have been taught continually that they must learn to think of dust-removal in its health rather than its economic relations. But the influence of the contractor and the force of custom have always stood in the way of any alteration of procedure. Mr. Millar's scheme will, we hope, revive the whole subject. Subject to regular removal from houses, the money cost of dealing with refuse is an important consideration, and it is obvious that every effort would be made to utilize the material in some way that would make as much return as possible for the money expended in its collection. Mr. Millar calculates that the metropolis now pays £120,000 annually for this purpose. If his scheme be such as to cost no more than this, it is even then worthy of consideration, for the removal from houses would not then be dependent, as now, upon the requirements of the brickmaker or the farmer.

Explosive Drugs.

The *Cinn. Lancet and Clinic* says it is well known that the manipulation of certain pharmaceutical remedies or their preparation, may through ignorance or carelessness give rise to explosions which, if they do nothing more, are calculated to make the manipulator seriously consider the desirability of changing his occupation. The list of them is rather formidable, and we may be doing a good service in bringing a few of them to the notice of the profession, the members of which have quite enough worries of their own to enable them to dispense with any unnecessary and avoidable sources of excitement.

Without alluding to the elementary precautions to be employed in the manufacture and dispensing of nitro-glycerine, the now fashionable remedy, thanks to the advocacy of Dr. Murrell, we may call attention to the liability of mixtures of chlorate of potash and sulphur to explode on percussion or attrition. This is a constantly recurring accident, and yet it is one known to every schoolboy. Further, a mixture of chlorate of potash and caoutchouc has been known to explode when used as a tooth-powder. Not

long since, the fall of a bottle of lycopodium in a chemist's shop at Strasburg was followed by an explosion, as a result of the highly inflammable powder taking fire at the gas-jet. Elsewhere a druggist who was engaged in drying some hypophosphite of calcium over a sand-bath was killed by the explosion. Oxalate and citrate of calcium are also liable to explode at a high temperature. Permanganate of potassium in combination with any organic substance is apt to explode spontaneously, and a mixture of chlorate of potassium, chloride of iron, and glycerine, has exploded in the pocket of the patient who carried it. A chemist at Paris prepared ozone with powders composed of equal parts of peroxide of manganese, permanganate of potassium, and powdered oxalic acid. Every precaution was taken, but the powders had not long been mixed before the bottle containing them was blown to atoms.

Quite recently a medical man wrote a doleful letter to a contemporary narrating his experience when endeavoring to manufacture terbene by acting on oil of turpentine with pure sulphuric acid. An explosion followed, and although, owing to his having taken care to envelop the bottle in a towel, nothing worse happened than serious damage to a new pair of trousers, he thought it his duty to warn others against this particular experiment.

Iodine, treated with ammonia, forms when dry a compound possessing violent detonating qualities, which has several times proved fatal.

Staining Wood.

On staining wood a writer in an exchange gives the following directions:

A good mahogany color can be had by dissolving maroon lake in water, adding a piece of potash about as large as a walnut to a quart of water, plenty of the color. This will give a good mahogany imitation on any wood, and can be used to darken the mahogany if so desired. Oak or ash may be stained brown by using linseed oil and benzine half and half, and burnt umber or Vandyke brown incorporated with this. Maple can be stained green grey by using copperas in water; oak will also be changed to a dark green blue through the same agency, the effect on ash being various shades of olive green. Ammonia applied to oak produces the bronze olive tint now used so much by architects. Staining by the fumes of ammonia results in all shades from light olive to the rich deep brown of extreme age. This method is considered the best for imparting to oak or mahogany the appearance of age; and for those wishing to avail themselves of an easy, clean, and certain means of gaining the result, fumigating offers no serious obstacle to its accomplishment, the articles necessary being easy of acquirement and at small expense.

Procure for your use a box sufficiently large to receive the article; any well-made packing box will be suitable, providing the joints or seams are close. Next get some strong full-strength liquid ammonia, not the diluted article of the druggist, pour some in a shallow receptacle—such, for instance, as a deep plate; place this in the bottom of the box, so that the fumes will rise and surround the object to be stained; close the box securely, so that the fumes will be confined as much as possible. When the article is small, of course the box need not be large—the smaller the better, for then you will not require so much ammonia. You can see how the staining progresses by wetting a portion from time to time; otherwise the change of color would not be perceptible. All that is now necessary is to leave the ammonia to do the work, remembering that the longer the exposure the darker the hue will be.

Mortality in the State of New York.

The total number of deaths during 1885, in the State of New York, was 80,407, of which 30,027 (or 37.3 per cent.) were of children under five years of age. The ratio per 1,000 of deaths from all zymotic diseases to the total mortality was 222.17, against 269.12 for nine months of 1884. This diminution was largely in typhoid fever and the diarrhœal diseases; the conjoined ratio per 1,000 from these diseases being 104.07, against 146.40 in 1884. As these are especially controlled by the public hygienic improvements, this indicates the efficiency of the sanitary work that has been done, and is emphasized by the ratio of diphtheria, which depends largely upon domiciliary conditions; namely, 56.06 per 1,000 total deaths in 1885, and 47.65 in 1884. These three typify the filth-diseases. There was no material change in the other zymotic diseases. Estimating the present population of the State at 5,400,000, an annual death-rate of 20 per 1,000 would give 108,000 total mortality. The reported mortality, with about 3,000 death-reports received after the bulletin is issued, and the mortality of Buffalo, account for about 88,000 deaths. During the year, about

5,000 more deaths were reported than in 1884, indicating that more local boards are organized, and that the returns are more complete.

Infantile Menstruation.

The *Semaine Médicale* publishes the history of a case, observed by Dr. Mengus, of a little girl of 23 months who menstruated regularly. The child was well formed and fully developed for her age. The menstrual flux proceeded from the genital organs; there was neither lesion, neoplasm, nor a foreign body to explain this. The hymeneal membrane was absent; examination could extend to the cervix uteri, which was excessively developed for a child of that age. After three days the catamenial flow stopped, and reappeared three weeks later on. The child presented signs of puberty, which increased after the second menstruation; the breasts were as developed as in the mobile period; the pelvis presented the signs of commencing puberty, and the skin lost the satin-like surface peculiar to children, and presented the rougher one characteristic of puberty in young girls; loss of blood weakened the child at first, but a few tonics restored her normal condition; she continued to menstruate regularly and have perfect health; she is now three years and a half old, precocious and intelligent, and measures 1.15 mètres in height, the stature of a child of seven. Her brother presents all the symptoms of cretinism.

Daltonism Amongst French Railway Officials.

Dr. Worms, medical officer to the Chemin de Fer du Nord, has recently published a report, and presented it to the Academy of Medicine. Among 1,173 railway officials whom he examined, in 224 the visual power for colors was imperfect, independent of any other lesion; 118 hesitated in distinguishing the different colors, 41 distinguished red easily, but confounded green, blue, and gray; 4 were perfectly color-blind; 63 confounded red, green, and gray. Those who presented an alteration of chromatic power sufficient to prevent clear distinction of signals, were not entrusted with the care of a train. The examination of railway servants before they are employed by the company, excludes men with Daltonism from being employed in running the trains. Dr. Worms states that the proportion of color-blind subjects was 5 per cent. Many others, however, did not distinguish colors clearly. These officials had been submitted to an examination previous to that made by Dr. Worms, who suggests that color-exercises should be included in public instruction.

Antiseptic Surgery.

In an able paper on this subject, recently read before the New York Academy of Medicine, Dr. Stephen Smith says:

"Cleanliness is the one great object sought to be attained in all operations. Whatever may be the final conclusion of scientific students as to the cause of putrefaction in wounds, practically it is determined that the surgeon may, with the most absolute certainty, protect an ordinary open wound from suppuration. To effect this object, he finds that he has simply to resort to those measures which are known to secure perfect cleanliness of the wound. The agents now relied upon and found efficient are:

"1. Soap and water to external parts.

"2. Carbolic solutions for the instruments.

"3. Bichloride solutions to all surfaces and tissues.

"4. Iodoform for external dressings.

"We may summarize the conditions regarded as essential to success as follows: that is, *a clean opeyator, clean assistants, a clean patient, clean instruments, clean dressings.*"

A Strange Disease.

According to the medical man who writes in the Chinese consular reports, near Changehow, "there is a form of hysterical disease or mania among adult males. The patient acquires the impression that his abdomen is inhabited by some animal, often a rat, whose excursions cause violent pain. Unheard-of efforts are made to expel the intruder, and often the savings of a whole family for a lifetime are wasted away on bonzes, sorcerers, and other quacks, in hope of obtaining relief for the sufferer. It is reported that in many cases death occurs from suffocation in the course of a violent convulsive paroxysm. The patient leads a double life, marked by the use of two voices of different timbres. As a rule his disposition alters in correspondence with the change of voice. Morally and mentally he is a different being in the two states. Whatever occurs during the period betokened by the unnatural voice is totally forgotten during the normal period."

Gonorrhœa in the Family.

M. P. Aubert contributes some facts to the *Lyon Médical* which show that gonorrhœa introduced into a family by the erring

husband may affect not only the wife, but children. Mme. X—— sent to him her little daughter, aged four, suffering from "whites," and Dr. Aubert found that she had gonorrhœa, with numerous gonococci in the secretions. The mother had herself suffered from excessive leucorrhœal discharge for several days, and she stated that her husband had had a discharge for some weeks. The family attributed it all, says Dr. Aubert, to some bad wine which had been used. In a second instance, father, mother, and little girl, all had the gonorrhœa. Here it was established that the mother, while suffering from the discharge, twice took her daughter into the bath with her. It was thought that the contagion came in this way.

Misfortune to the Graduates of the Jefferson Medical College.

After the college commencement, which was held on April 2, the Faculty gave a banquet to the newly-made doctors at Natatorium Hall. A temporary floor had been placed over the basin fixed for swimming in the west end of the room. On the temporary floor stood a piano, around which a number of doctors were standing. Suddenly the floor gave way, and about twenty-five of the party fell with the piano and the débris to the bottom of the basin, a distance of twenty feet. Three persons were seriously hurt, but there was no fatal injury.

Polygonum Aviculare.

Dr. Roschtschinin, of St. Petersburg, at the late Congress of Russian Physicians, spoke highly of the value of Polygonum aviculare (L.) in bronchial catarrh and asthma. According to the investigations of Werner, the plant contained considerable quantities of an alkaloid. The speaker employs an infusion of the plant, 30 grm. pro litre, of which a glassful was to be taken thrice daily with milk, kefir, or sweetened water. Chronic bronchial catarrhs were said to disappear in from 10 to 30 days. It was also useful in whooping-cough, but of no service in phthisis, although it was largely used as a vulgar remedy for the disease in Russia.

A Curious Trial.

A singular case has just been decided by the Paris Civil Tribunal. Dr. Peyrol, head surgeon at the Hôtel-Dieu, claimed 800 francs for extracting a bullet from Mme de Beauregard, who had accidentally shot herself. The claim was disputed on the ground that the plaintiff stated erroneously that the bullet was lodged in the right thigh, besides which, she had been attended by two other medical men. The tribunal overruled the plea, believing that it mattered very little whether the bullet was on the right or the left side, so long as the patient's sufferings had been relieved; and the medical man therefore won his suit.

Items.

—Bronzes, or more correctly, metallic powders resembling gold dust, were invented in 1648, by a monk, at Furth, in Bavaria. He took the scraps or cuttings of the metallic leaves, then known as Dutch leaf, and ground them with honey. This roughly-made bronze powder was used for ornamenting parchments, capital letters in Bibles, choral books, etc.

—It is said that there are at present at the various German universities no fewer than 157 professors between the ages of seventy and ninety. Of these, 122 deliver their lectures as usual. The oldest is the veteran Von Ranke, the historian, who is now in his ninetieth year, but is not considered fully equal in vigor, memory, and other faculties, to Professor Elvenich, who is thirty-nine days his junior.

—"I say, doctor," said a citizen, "do you know how Jim Bullard is getting on since he left town?"

"Jim was shot and killed, poor fellow, only last week."

"Is it possible!" exclaimed the shocked citizen; "where was he shot?"

"In the lumbar region, I believe."

"In the lumber region? Why, I understood that Jim had gone to the oil region."

—A woman once consulted Abernethy for an ulcer on her arm, and when asked, "What ails you?" exhibited the sore without speaking. "Poultice it, and take five grains of blue mass every night; come back in a week!" The woman offered the usual fee, which the surgeon refused. At the end of the week the patient appeared, and the same pantomime occurred. After a few more visits, the doctor looked at the arm and pronounced it well. The patient again offered a fee. "No," said Abernethy, "I will take nothing. You are the most sensible woman I ever met. *You don't talk!*" A few months afterwards he discovered that the woman was *dumb*.

MARRIAGE.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*

2d. *All materials weighed with scrupulous exactness.*

3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*

4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superintendent and his assistant, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful Home.

CONGENITAL DISLOCATION OF THE HIP-JOINT—EXCISION OF THE HIP-JOINT.*

BY H. R. WHARTON, M. D.,

Surgeon to the Children's Hospital, Instructor in Clinical Surgery in the University of Penna., Assistant Surgeon to the University Hospital.

The first case I shall bring before you to-day, is this little girl, five years of age, whom I will ask to walk to the table so that you can observe her method of locomotion.

You notice she walks with a decided limp on the left side, and also that there is tilting of the pelvis, and that her gait is a peculiar waddling one.

I now have her undressed, and ask her to stand upon the table, and you see that the left limb is decidedly shorter than the right, and that when the weight of the body rests upon the left foot, the pelvis is tilted. You see also a projection of the left buttock, most marked a little below and behind the anterior superior spinous process of the ilium, and that the limb is adducted, so that the deformity we have here clearly resembles that seen in the third stage of hip-joint disease. In addition, on examining the most marked portion of the swelling, just mentioned, you see that there is some redness of the skin, and upon palpation I can detect a sense of fluctuation, so that the appearances are strongly those of an abscess, which is not an uncommon complication in the stage of coxalgia of which this patient presents the symptoms.

Now, when I place her in the recumbent posture, and grasp the affected limb firmly, and make extension, you see that I am able to overcome the shortening, and you will also notice that the projection on the buttock has in a measure disappeared.

I am also able to abduct, adduct and circumduct the limb, and to flex it by the use of little force and without causing the patient the slightest pain.

If I now withdraw the extending force, the shortening re-appears, and also the marked prominence on the buttock; and upon examining further, I find that the great trochanter has assumed a position behind and below the anterior superior process of the ilium, as may be proved by measurements according to Bryant's or Nelaton's line.

The prominence here upon the buttock is due to the head of the bone in this abnormal position, and also the development of an adventitious bursa in the tissues over its location, so that, I think, we have here a case of the so-called congenital dislocation of the hip-joint, and not one of coxalgia, as might, upon a superficial examination, be supposed. In this diagnosis, Prof. Ashhurst, who examined the case yesterday and referred her to the clinic to-day, concurs.

As regards the pathology of this so-called dislocation of the hip-joint, I think at the present time that all authorities agree that it is due to a malformation or want of development of the acetabulum which allows the head of the femur to slip upon the dorsum of the ilium, the capsular ligament being much lengthened and thickened.

The older theories of its production during fœtal life by uterine contraction and that of its traumatic origin during labor are

* Delivered in the Children's Hospital.

now generally disregarded, for if due to either of these causes, the head of the bone would be outside of the capsular ligament, which is proved not to be the case in the specimens that have been carefully examined post-mortem.

This condition is not generally recognized until the child begins to walk, and is then often mistaken for coxalgia, a mistake one might easily make unless a careful examination were made. You noticed the awkward gait this child exhibited in walking, and this is even more pronounced when both hip-joints are involved—when the waddling gait is most characteristic. When these cases are allowed to go about without any apparatus, we have developed a compensating spinal curvature from the tilting of the pelvis.

As regards treatment, the result to be obtained is not very satisfactory; various apparatus has been devised with the object of fixing the head of the bone in its normal position, and allowing a certain amount of motion so that it might form for itself an articular cavity in which the head of the bone might rest and be held by the thickening of the surrounding tissues. Dr. Buckminster Brown, of Boston, has reported one very good result of this kind, but the time and apparatus required to obtain such a result would only render it possible in a few selected cases.

The wearing of a pelvic belt with pads so arranged as to fix more or less completely the head of the bone has been recommended, but upon the whole, I think that those who have had the most experience with these cases advise the use of a high shoe on the affected limb to prevent tilting of the pelvis and its consequent compensating spinal curvature, and rest in the recumbent posture for a portion of the day.

So we will order for this little girl a shoe with a sole and heel one and a half inches high, and after she has worn it for a month we will ask her mother to bring her back to the hospital, so that we may see the result of the use of this appliance.

EXCISION OF THE HIP-JOINT.

The next case I bring before you is this little girl, aged nine years, who has been a patient in the hospital for some months, being admitted during the latter part of the summer suffering from coxalgia of the left hip-joint complicated with an immense abscess which occupied the anterior and lateral regions of the thigh. After her admission this was evacuated by aspiration, and she was put to bed with extension, but the abscess refilled and was then treated by a free incision and the introduction of drainage-tubes to secure free exit for the purulent matter.

The purulent discharge was very profuse, and as the child began to show marked symptoms of exhaustion, the question of excision of the hip was considerered at this time; but as the weather was very warm, an unfavorable condition for operation in this class of patients, we thought it better to defer operative interference at the time. Fortunately, she improved slowly from this time in her general condition, and she now has arrived at that point where we think the operation of excision of the hip may be performed with a fair chance of benefiting her condition.

You will notice on examining the case that there are several openings from which pus is discharged, one just below the great trochanter and one on the anterior surface of the thigh, which represents the point of opening of the large abscess of which I spoke. You will also notice marked deformity of the affected limb, which consists in great shortening and adduction of the limb, with eversion of the foot and a prominence upon the dorsum of the ilium, which is due to the fact that there has been in this case a spontaneous dislocation of the femur.

This spontaneous dislocation of the femur in the latter stages of hip-joint disease is not an uncommon accident, and is due to several causes, namely, to separation of the head of the bone at its epiphyseal line, to distention of and ulceration of the capsular ligament, and to muscular action combined with these conditions. Mr. Barwell remarks upon the suddenness of its occurrence, and this has been my experience, and in this case it occurred in the intervals of my daily visits.

The patient being etherized and turned upon her side, I will make the excision to expose the head of the bone, and the incision I make here is the one recommended by Heyfelder, and is the one we generally use in this hospital, as it gives a free exposure of the part to be removed, and leaves a wound, the edges of which can be brought into nice apposition.

It starts a short distance above the great trochanter, parallel with the fibres of the gluteus maximus muscle, is carried down to the great trochanter, then in a curve below it, and is brought forward to the line of the femur, and is finished by a straight incision. I now expose the great trochanter, and in dividing the muscles inserted into it and any fibrous adhesions which exist, use a probe-

pointed knife. Having divided these by manipulation of the limb, I next turn the head of the bone out of the wound. I now remove the head of the bone and great trochanter by sawing across the femur just below the great trochanter with a metacarpal saw, and you notice in examining the part removed, that the head and neck of the femur are represented only by an irrregular mass of carious bone. I now explore the acetabulum, and find in it the separated head of the bone, which I remove with my fingers; as the acetabulum seems perfectly healthy, it requires no treatment. If I found carious bone in this location, I would remove it freely. I now round off the sawed end of the femur with bone forceps, and bring the thigh down into position, and find enough bone has been removed to allow the limb to be placed in fair position.

I now tie several small vessels which bleed, and you will notice that the amount of blood lost during the operation has been very small. I now wash out the wound with a one in forty solution of carbolic acid, and introduce a drainage-tube and bring the edges together with a few points of interrupted suture, and then apply an antiseptic gauze dressing and hold this in position by broad straps of adhesive plaster.

An adhesive plaster extension apparatus is now applied to the leg, and the child is put into her bed and lateral support is given to the limb by means of sand-bags. You notice the limb is kept well abducted, an important point in the after-treatment of these cases, and as the patient exhibits some symptoms of shock resulting from the operation, her temperature will be maintained by surrounding her with hot water cans, and she will be given small doses of carbonate of ammonium at frequent intervals, with the object of overcoming this condition.

The after-treatment of these cases consists in dressing the wound as frequently as is necessary, and keeping the limb in good position.

The results obtained after excision of the hip-joint are usually good, as regards the usefulness of the limb, and our object is to obtain fibrous union of the sawn surface of the femur with the pelvis in the region of the acetabulum, and by this means to secure a fairly movable false joint at this position. To encourage the formation of this as soon as the wound is solidly healed, we will practice passive motion, and encourage the patient to move the limb with the same object in view.

The immediate results of excision are generally very good, but in a large number of completed cases you will find that the mortality is not insignificant—many cases dying of exhaustion, following the profuse suppuration, or of visceral disease, the result of this; and in some cases recurrent caries occurs in the femur or acetabulum, for which a re-excision has been performed with satisfactory results.

In view of the mortality resulting from this operation, and it is a serious one in cases whose constitutional condition is such as you see here to-day, we in this hospital do not practice early excisions, but reserve the operation for cases in the later stages of the disease, when the patient's life is endangered from this cause, or when, as in the case you have just seen, there is great deformity associated with the previous condition, which, even if recovery took place, would leave the patient with a useless limb.

So that upon the whole we adopt a conservative method of treatment, endeavoring to obtain a cure if possible, even if some deformity results, and when the active symptoms of disease have subsided, we then correct this deformity by means of subcutaneous osteotomy of the femur in Gant's line, that is just below the lesser trochanter of the femur, which is a comparatively safe operation, and gives excellent results as regards the usefulness of the limb.

[This case was shown in the clinic a month after the operation, with the wound of excision solidly healed; the only point remaining open was the sinus on the thigh, from which a small amount of pus continued to escape. There was a fair amount of motion in the new false joint, and her general condition had much improved.]

Communications.

AN ADDRESS DELIVERED AT THE ANNUAL COMMENCEMENT OF THE MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.*

BY FRANK WOODBURY, M. D.,

Professor of Therapeutics, Materia Medica, and Clinical Medicine in the Medico-Chirurgical College.

Mr. President, Ladies, and Gentlemen: It is an honor to be here. No ordinary occasion now engages our attention; no summer-day pastime, which these flowers and sweet strains of music are meant to

* Delivered at Association Hall, Philadelphia, April 3, 1886.

gracefully adorn; but it is a solemn ceremonial at which you have been invited to assist. The deep significance of our proceedings is realized by these successful candidates who have been crowned in your presence; but still more is it felt by the Faculty, who have labored long and earnestly, in order that these shall be found fully prepared for the responsible duties which await them. The honorable Board of Trustees of the Medico-Chirurgical College, upon recommendation of the Faculty, have conferred upon each the degree of Doctor in Medicine, with all the honors, rights, and privileges thereunto pertaining. Their authority for so doing is derived directly from the Legislature of this Commonwealth, to which they are also responsible for its proper exercise. Among the rights conferred by the trustees, as witnessed by the diploma now in the hands of each of these graduates, is the right to practice medicine in the State of Pennsylvania. The diploma itself being the license to practice, it need only be registered at the prothonotary's office in order to allow its possessor to engage at once in the active duties of his profession. Owing to the preliminary examination required by this institution, and its three years' graded course, its diploma is also recognized elsewhere; for instance by the State Board of Health of Illinois, which refuses to acknowledge the diploma of those colleges which graduate students at the close of the second year's study, and which exact no preliminary examination.

The Legislature of Pennsylvania has not only required of the medical colleges of this State that they shall determine and pronounce upon the fitness of their own students, but as the law has been interpreted by the Supreme Court of Pennsylvania, they are also made to judge and pass upon the standing of all physicians graduating from foreign schools who wish to enter upon practice here. After examination, if they are found worthy, their diplomas must be endorsed by the dean of the faculty before they can be registered. Failure to do this is visited by a heavy penalty by the law.

The burden of responsibility resting upon Trustees and Faculty, is therefore no light one, and it is both gratifying and encouraging to us to have such an attentive and appreciative audience to assist in this ceremony.

And yet, such occasions are no novelty to the citizens of Philadelphia. More than a hundred years ago—nearly a century and a quarter—the foundation of the first medical school in this country was laid in this city, by Drs. Wm. Shippen, John Morgan, Adam Kuhn, Benjamin Rush, and Thomas Bond.

"The men of old built well."

Witness the present high standing of the Medical Department of the University of Pennsylvania, now 121 years old. Witness our other great school, founded in 1825, by George McClellan, the Jefferson Medical College, which has probably the largest number of living graduates in medicine of any college in this country. Witness our more recent accession, the Women's Medical College, which is doing more to fit women for the higher walks of the profession, than any similar institution in the world;—it is, I am happy to say, successful and prosperous, and deservedly so.

During the century and a quarter, with but few exceptions during the dark days of the Revolution, annually have the colleges called upon the community to aid in this public ceremonial. In that time, nearly twenty thousand graduates in medicine have gone out from these schools to all parts of the world, carrying to all lands the testimony of proficiency of their teaching, and broadly publishing the many attractions of our City of Brotherly Love. Well did William Penn describe it. He said: "Of all places in the world, I remember not one better seated."

You do well to cherish your medical schools. They bring every year hundreds of young men to this city to form acquaintances and friendships which are not broken by separation, but serve as bonds securely binding Philadelphia with other parts of the Union, thus establishing firmly its old-time position as the Keystone State. Not only have they encouraged strangers to visit the city, but the Colleges by their very existence have stimulated the growth of hospitals and dispensaries, and charitable work among the sick and needy, so that it can truly be said that no one in this city is so poor as to be unable to obtain medical care in sickness, and proper treatment, if he desire it.

Indeed, the medical schools and clinical opportunities of Philadelphia are not without a reflex influence upon the doctors themselves. It does us good, at times, to see ourselves as others see us; and I therefore, without affectation, may repeat what Mr. Bancroft has so well said in a recent article in the Century Magazine. (Article on Henry Clay, etc.) "Philadelphia, seemingly by some divine right of succession, has always a constellation of men, adepts in the science of life, and alike skilful and successful in practice."

I would not dare attempt to read over the long list of the distinguished physicians, who in the past have graced your annals, nor attempt the invidious task of sounding the praise of those who are now most prominent in maintaining its old-time reputation as the Mecca of American medicine. Nor would I, as *laudator temporis acti*, forget the obligations of the present Medicine is a progressive science. The times change, and we are changing with them. The science of medicine is not to-day what it was one year ago, much more is it not what it was a decade or a score of years ago. The advance in our knowledge of the nature of the disease within only a few years has been little short of marvelous. May I briefly indicate some of the more prominent traits which characterize modern medicine, and, incidentally, show how, in some respects at least, the problems presented to physicians of our own day involve peculiar responsibilities, and differ from those not only of the ancients, but from those of even the preceding generation?

In the first place, medicine has been taken from the realm of metaphysical disquisition, and is now firmly established as a branch of natural science. It has no laws at variance with those of the other inductive sciences, it recognizes no infallible dogma, it belongs to no "pathy," and acknowledges no "ism," it is neither "old school" nor "new school," but if some title is needed to distinguish it, let it be called RATIONAL MEDICINE. It admits no exclusive right to use particular remedies, and will permit none. When the question of the propriety of introducing homœopathy into the Medical School of Naples was presented some years ago, the faculty replied: "The University of Naples is not a proper field for instruction in homœopathy, because the rational system which is imparted here, on the basis of the natural sciences, excludes allopathy, as well as homœopathy, or any other absolute system or dogma. The study of rational medicine is as far removed from the ancient allopathy, with its blood-letting and purgation, as from the recent delusion of homœopathy, with its ridiculous infinitesimal doses and similia similibus medication."* I need not, after this, assure this audience that allopathic medication is not taught at the Medico-Chirurgical College of Philadelphia, any more than it is at the University of Naples.

In ancient Egypt the manner of treating diseases was established by law. The physician was obliged to conform his practice to the precepts of the sacred books, and was not permitted to change anything. To insure conformity it was decreed that, if by following this method he was unable to save his patient, he was not held responsible for the result; but if he departed from it, and the sick person happened to die, he was punished with death.* How great the contrast, with our present method! Medicine is now unfettered by such restrictive laws. Perhaps it may be thought that too much recklessness is sometimes displayed, and procedures adopted which are not directed by the single motive of the best good of the patient. Too often in such cases the operation is classed as a brilliant success—but the patient dies.

Rational medicine belongs to our own day, since in every age of the world medical science has been obliged to keep pace with other sciences, and the slow growth of intelligence in the process of civilization. The physical sciences, upon which our studies are most dependent, biological chemistry, physiology, and applied physics, have only within our own day attained a sufficient degree of perfection to give support to a system of medicine deserving the name of rational. It was only a year or two ago that the question of spontaneous generation was forever settled by the genius of Pasteur. I need not repeat the familiar story of the labors of Schwann, of Cohnheim, of Koch, of Obermeier, and a host of others in the field of microscopic botany, which have proven conclusively that in the acute infectious diseases generally, there are present in the blood of the patient, or the tissues, or both, microscopic organisms which are classed under the general title of bacteria, of various shapes and sizes, and belonging to the simplest vegetable forms. Not only have they been found in infectious diseases, but in others which are not ordinarily considered as such, like consumption.

The exact manner in which these bacteria act, if they are active, is unsettled; it is probable that they not only rob the blood of pabulum, and by their presence produce irritation and obstruction in the blood-vessels, but they also secrete or excrete in their processes of development certain substances which are highly deleterious to the human body. One of the most interesting and important problems before physicians to-day is, how may the susceptible human system be so modified as to enable it to successfully resist the development of the bacteria, so that the micro-organism may find in it no congenial

*Quoted from Physiology; Preliminary Course Lectures by J. T. Whittaker, M. D., Cincinnati, 1879, page 15.

*Diodorus, lib. i., p, 74.

soil for its development. We know that a patient with bronchitis is more liable to have tuberculosis than if no lesion existed; we know that a man with an exhausted nervous system is more liable to typhoid fever than a man in his normal condition; youth favors the appearance of eruptive fevers; residence in certain localities predisposes to malarial affections, etc.

Now, if men may become predisposed to disease, they may also be rendered indisposed or insusceptible to its influence. Towards this problem of protection from infection much study is now directed. Pasteur believes that he is able to make any one proof against receiving infection from the bite of a mad dog, just as Jenner taught how to vaccinate against small-pox. Researches are now going on in Brazil and Mexico into the protection from yellow fever by means of inoculation; and last year thousands of people in Spain were inoculated with cholera virus. I am informed that in Paris researches are now being conducted in investigation of the question of similar means of protection against diphtheria. The results of these experiments are anxiously looked for; their results upon medical practice I will not predict. Whatever may be the outcome, however, it is certain that epidemics of infectious diseases may be stamped out by other means. During the severe epidemic of small-pox which prevailed last winter in Montreal, where a large proportion of the population was opposed to vaccination, the adjoining communities were threatened by the disease. By the prompt action of the Boards of Health of New York and other states, the epidemic was stayed at their border by proper hygienic precautions, and it obtained no foothold in New York or in adjacent states. It is upon the intelligent appreciation of the laws of sanitary science by the people, and their willing aid in enforcing them, that we now rely when threatened by an epidemic whether of cholera or small-pox. Owing to improved sanitation the plague has disappeared from Europe. Epidemics are no longer regarded as visitations of the wrath of Divine Providence as a punishment for moral sins, but for physical ones. I would here call attention to the Sanitary Convention soon to be held in Philadelphia under the auspices of the State Board of Health, which is calculated to render great public service by directing general attention to the value of sanitary legislation.

Modern medicine has not only overcome epidemics, but it presents more hopeful prospects to sufferers from diseases hitherto regarded as beyond the reach of art. Jaccoud has shown that consumption is curable. Flint, whose recent death was such a severe loss to the profession, demonstrated that heart disease need not shorten life; typhoid fever, by modern methods, is very amenable to treatment; diabetes and Bright's diseases of the kidneys are no longer regarded as death-warrants, nor as necessarily debarring from active life. Locomotor ataxia and various paralyses which had been regarded as hopeless, have been successfully treated, and helpless invalids restored to health and usefulness. I will not detain you with the triumphs of modern surgery, the ease and safety with which abdominal tumors have been removed, the exsection of cancer of the stomach, or the wonderful operations upon the brain. I will merely say that modern medicine is distinguished not only by its scientific methods and achievements, but also by its appreciation of the importance of other agents than drugs in the treatment of diseased conditions. Everything in the daily life of the patient that can influence his health for good or ill is made the subject of careful scrutiny; his habits, his dress, occupation, food, and surroundings generally, are all passed in review, in order to determine the disturbing element, as a necessary preliminary to its removal; disease being now defined as a disorder or disturbance in the course of physiological life.

There is a problem which has not yet received the attention which it deserves, which I would discuss at some length had I the time and were this the place to do so; it is the influence of the imagination upon the body, and its rational employment in the treatment of disease.

Let us for a moment consider the question of the application of this force in causing and removing disease.

Strictly speaking, disease means a disordered state of the feeling, which may or may not be attended by bodily change. For instance, a patient will complain after amputation of his foot, that his corns still hurt him. Clearly, in this case it is a mental corn that is giving him pain. If you will pardon the illustration, let me ask if this is not the case in every lesion attended by suffering? Not only is there a local injury, but there is also, in direct connection with it by means of nerve tracts, a centre in the brain, which is thrown into activity, and the consciousness thereby becomes disagreeably impressed by a perception of pain.

This centre may be thrown into activity independently of external stimulus, and

pain be felt without a wound; or it may have its activity reduced, and no pain be felt, although a wound be inflicted. It is not generally known that the discovery of anæsthesia by ether, by Morton, checked completely, at least for a time, the growth of painless surgery without anæsthetics. I mean that by the aid of procedures the import of which was not well understood, it had been shown conclusively that many persons could be thrown into temporary unconsciousness, during which state of inactivity surgical operations might be performed without causing them to experience any pain whatever.

Elliotson reported a number of surgical operations done under what he considered as animal mesmerism or magnetism, but which is known as hypnotism at the present day.

In 1856, Dr. Esdaile reported 261 operations performed by him in the hospitals of Hooghly and Calcutta; and many others have been published since then. Repeated trials of this method have now shown that this method is applicable in many cases, and should be made the subject of further investigation. Its superiority over chloroform or ether, for short operations, such as the extraction of teeth, is very obvious, since it is entirely free from danger, and the patient can be restored at once to consciousness, and there are no after effects. In producing this condition, it is well known that the imagination is largely instrumental, as John Hunter was able to determine in his own person.

Physiology teaches that to some extent nutrition is influenced by the mind, and the various sensory, motor, vaso-motor, and trophic nerves, may have their action excited, perverted, or depressed, and thus bring about changes in sensation, muscular contraction, nutrition and secretion.* Disease, even death, has been caused simply by emotion, or by a purely mental state; and as the greater includes the less, we must admit the influence of the imagination upon the body in producing disease. Unzer, in his great work published in 1771, says: "Expectation of the action of a remedy often causes us to experience its action beforehand." This is analogous to the sour taste in the mouth when thinking of lemons, or the nausea excited by the thought of cold drawn castor-oil.

Dr. Oliver Wendell Holmes, in the course of some after-dinner remarks, at a reception in Boston at which I was present, said, apropos of old-fashioned doctors, that "when I was a boy I constantly lived in mortal dread of one thing—a dose of ipecac. It was the bane of my existence, and even now in the midst of a dinner party the thought of it makes me sick." He went on to state that a certain doctor with a face that was so yellow that it was almost the color of rhubarb, and who smelt of rhubarb, and who drove a dusty yellow gig that suggested rhubarb as soon as it came in sight, was in the habit of always giving the boys, when anything was the matter with them, a dose of ipecac followed by rhubarb. The mere recollection of it nauseated him half a century afterward.

Without pursuing this train of thought further, allow me to make the deduction that an agent which can modify sensation, motion, secretion, and circulation, so as to cause disease and even death, may be usefully employed in the treatment of disease by those who are wise enough to use it. Let me give an illustration. When Humphrey Davy was making some experiments upon patients with nitrous oxide gas, he placed a small pocket thermometer under the tongue of a patient afflicted with paralysis: the patient, mistaking the thermometer for a talisman, almost immediately said that he felt better; Davy requested him to return the next day, when the same routine was observed, with still greater improvement. This was repeated, says Dr. Paris, every succeeding day for a fortnight, the patient gradually improving during that period, when he was dismissed as cured, no other application having been used.*

The cure of this case was brought about by expectant attention combined with faith and hope, and similar instances abound in medical history. All the cases of healing by the Royal Touch were not impostures; Perkin's tractors did restore many to health, and so did the imitation wooden ones of Dr. Haygarth; metallo-therapy was not a deliberate attempt at deception, nor is the faith cure. The question naturally arises if the effects of medicines can be obtained without administering drugs, why do we continue to order our patients to take more or less nauseous medicine. The answer to this is, that the imagination is all-powerful within certain limits, which it is our duty to investigate and define; outside of these it is not, and there is still a wide field for usefulness of remedies skilfully administered.

* Illustrations of the Influence of the Mind upon the Body in Health and Disease Designed to Elucidate the Action of the Imagination. By Daniel Hack Tuke, London, 1884, 2d edition. A work which every thoughtful physician should be familiar with.

* Paris Pharmacologia, quoted by Pettigrew, Medical Superstitions.

A most interesting problem in connection with this is the scientific application of the imagination to *assist* the ordinary remedies in treatment of disease. Dr. Rush is reported as saying that he never gave a medicine without first sitting down and describing in detail the effects which the prescription was intended to produce. His observation had taught him that by following this course he had been much more successful in obtaining desired results, than when the patient was kept in ignorance of his object.

If a morbid condition can be cured by a mental impression alone, it would be morally wrong to give medicine, except for its mental effects.

"Canst thou minister to a mind diseased?
Then throw physic to the dogs."

Under such circumstances physic, beyond all question, should be thrown away; it is the physician's duty to minister to the diseased imagination; if he cannot, he is not fit for the responsible duties of his profession. In other cases, to which more or less of a physical element in the form of bodily ailment is added, the disease may or may not be curable by the same means; but in every case, except in very young children and idiots, or insane, the physician is brought in immediate contact with the mental element of disease, and he should recognize it and give it due consideration in his treatment.

Gentlemen of the graduating class of 1886: Through years of patient toil and arduous preparation, you have been sustained by the bright prospect which to-day is realized. I bid you, on behalf of this brilliant audience and the trustees and faculty here assembled —welcome to the medical profession. Keep your honor bright, stoop to no mean or unprofessional act,

"To thine own self be true;
And it must follow, as the night the day,
Thou canst not then be false to any man."

It was a poetical thought of the ancients that wherever a Greek colony was established, there was Hellas. So I bid you carry with you the thought, that wherever you go you are henceforth an integral portion of the profession; that you are individually responsible for its welfare or disgrace within the limits of your capacity, to serve it or to shame it. Do not dread adversity. Holmes has well said, that "There's no success possible without opposition. Force is always aggressive, and crowds something or other." Subjugate self to your ambition, and let your highest aim be to render yourselves useful.

The times need men—men who their duty know, and are determined that it shall not remain undone. Your fellow-man needs you —go into a world full of suffering and sorrow, and bind up wounds, soothe the aching brow, restore those who are down-cast, make the deaf to hear, the blind to see, the lame to walk. Bear ever in your mind the dignity of your calling, knowing, as the old Roman has said—

"In nothing do men approach so near to the Gods, as in giving health to man."

NEURASTHENIA.

BY C. C. THAYER, M. D.,
Of Clifton Springs, N. Y.

The dead often teach the living what life never reveals; but there are some diseases and disorders which flesh is heir to, not illuminated by any side-lights from the dead-house. Especially is this true of the heterogeneous forms of functional disorders of the nervous system, most of which present no tangible lesion, or morbid anatomy, but a complexity of symptoms, and an indefinite pathology. From this field of asthenology we have selected neurasthenia—nerve debility, nerve exhaustion—for contemplation and discussion at this regular meeting of this Medical Association.

DEFINITION.

Neurasthenia, from neuron (nerve), and astheneia (strengthless). Aristotle said, "Define your terms, and discussions cease." A clear definition of the *nature* of disease is a "sine qua non" in its intelligent management. Medical literature on this subject, until recently, has been noticeably deficient and defective. From time to time various able articles have been written on this subject, or at this subject, under quite diverse titles, and illustrating a great diversity of thought as to the true nature of the disease. Some of these incongruous titles are as follows: "Nervousness," "Functional weakness of the spinal cord," "functional debility," "exhaustion of spinal cord," "spinal irritation," "nervous debility," "nervous dyspepsia," "spinal anæmia," "spinal hyperæmia," etc. This diversity and indefiniteness are neither strange nor blamable. The same is true of the early history of most diseases both as to their nomenclature, their pathology, and their symptoms, while their treatment never ceases to change. If Prof. Bouchut considered this disease as "nervousness," and Erb as "spinal irritation," and Althaus as "spinal exhaustion," and Brachet as "nerve spasm," and Flint as "functional debility," etc., they in-

deed saw what actually existed, though each may not have seen all. Their views were diverse, and symptoms often taken for diseases, yet these and other experts builded better than they knew even, and laid permanent foundations for further scientific illumination of the nature, classification of the symptoms, and valuable suggestions of means and methods of the treatment of this disease; and let him who can, do more.

SYMPTOMS.

In defining or describing neurasthenia, what symptoms may we find? Every kind; though not all in any one case.

Allow me here to introduce the clinical history of one of many under daily treatment in this sanitarium (Clifton Springs). Age twenty-four (neurasthenia is a disease of mid-life); single; dark complexion; bilious-nervous temperament; skin pale, dry, and variable in temperature to the touch, made hot or cold by slight change of air or excitement; pulse weak, nervous, and variable (about 85); the thermometer temperature normal; tongue large, pale, and trembling; dyspepsia; cold extremities; urine loaded with phosphates, and sometimes oxalates; irritation of bladder, sometimes difficulty of voiding the urine; irritation of ovaries; menses scant; bowels constipated; abdomen flat and hard; appetite capricious; defective vision; dilated pupils; palpitation of heart; roaring in ears; oppressed breathing; a wavy "rushing of blood to the head;" sore or tender scalp; insomnia; voice weak and high in pitch; fear of crowds; an internal trembling or "crawling," and a desire for stimulants.

This patient exhibited all the above symptoms, though not all at the same time.

Dr. Geo. Beard, in his exhaustive treatise on "Nervous Exhaustion," mentions many of the above, and some others, to which I will call your attention: "Headache, congestion of conjunctiva, defective mental control, hopelessness, fear, defective thirst, salivation, podalgia, dysphagia, sense of exhaustion, yawning, rapid decay of teeth, pruritis, and surface paralysis." What an array of symptoms! and yet with equal propriety we might add many more, in fact, any functional symptom may not be considered inappropriate or illegitimate. How, then, may we arrive at an intelligent

DIAGNOSIS?

By the process of exclusion, or differential diagnosis. What diseases are likely to be confounded with neurasthenia? In "Ziemssen's Cyclopœdia" Prof. Erb says: "It cannot be denied that this complaint has a close resemblance in many respects to spinal irritation, ... and the opinion might perhaps be defended that this disease is essentially for the male sex that which corresponds with spinal irritation in females." That Prof. Erb's "neurasthenia spinalis" can be limited to the *spine* is not so clear. As clear to suppose that the root of a tree may suffer exhaustion, without a corresponding exhaustion of branches. If the neurasthenia spinalis stands for general nerve exhaustion, the subject in hand, then its comparison and essential relation to spinal irritation needs analysis.

That spinal irritation is more than a *symptom* has been denied by many since the able investigations of Dr. Brown, *Glasgow Med. Journ.*, 1828. Prof. Erb, of Heidelberg, one of Germany's ablest neurologists, and others, declare for its individuality; while Stilling refers it to hyperæmia of the cord, Hammond to anæmia of the cord, and Hirsh to some dynamic disorder or irritation which may be due to very different causes. But whether spinal irritation be an individual disease or not, should it ever be confounded with nerve exhaustion? Never, if we bear in mind the ever-distinguishing feature that spinal irritation is characterized by *sensory irritation*, neurasthenia by *motor debility*.

Again, dorsal pains, muscular contractions, and sensitive vertebræ, are prominent and ever-present symptoms of spinal irritation, but not of neurasthenia. And again, in spinal irritation the symptoms are more local, in nerve exhaustion they are more general, varied and complex.

Some have confounded neurasthenia with hysteria. Hamilton has well said "that hysteria simulates a multitude of organic and functional diseases so perfectly," and Beard occupies nearly two pages in showing their dissimilarities, that it may not seem folly to make an otherwise needless remark, that, with a careful consideration of the general and clinical history, muscular paroxysms, mental illusions and hallucinations, tempestuous transitions of tears and laughter, clavus hystericus and globus hystericus, none need to confound hysteria with neurasthenia.

There is another disorder, by far more liable to be confounded with nerve exhaustion than either of the above, and that is nervous dyspepsia. The pale dry skin, gastric and intestinal disorders, cerebral and cardiac disturbances, insomnia, and sense of oppresion, are quite likely to produce confusion, and this confusion is worse confounded by the fact that chronic functional atonic dyspepsia

has a similar pathological condition, and is usually a prominent complication of neurasthenia. How then shall we diagnose the latter with dyspepsia as a complicating symptom, from dyspepsia as a primary and unassociated disease. The following symptomatic comparison will aid in the differential diagnosis:

Neurasthenia.	Dyspepsia.
As a rule does not result from gastric disorders.	As a rule does result from gastric troubles.
As a rule does not present prominent stomach troubles.	As a rule is attended with pyrosis, fermentation, cardialgia, etc.
As a rule presents nervous *debility*.	As a rule presents nervous *excitability*.
As a rule is attended with a feeble, but regular appetite.	As a rule is attended with a capricious appetite.
As a rule does not diminish flesh.	As a rule diminishes flesh.
As a rule does not produce purely mental disorders.	As a rule produces hebetude, depression, and fear concerning heart, kidneys, etc.
As a rule is attended with phosphatic, and often with strong alkaline urine.	As a rule is attended with lithates, urates, and often strongly acid urine.
As a rule is attended with normal secretions and excretions.	As a rule is attended with abnormal secretions and excretions.
Is a kind of paralysis.	Is a kind of a diacrises.

There is still another condition likely to confuse one in the diagnosis of neurasthenia, and that is anæmia or better oligæmia, signifying not a *lack* of blood, but a *poverty* of blood.

The cold, pale surface, the weak voice, low pulse, reduced strength, ringing in the ears, palpitation and mental incapacity, are all prominent symptoms of nerve exhaustion, as well as of oligæmia, but there are two pathognomonic symptoms that decide in the differential diagnosis. In nerve exhaustion *poverty* of blood is not characteristic; in anæmia it always is. In nerve exhaustion there is no "cardiac bruit," or "venous hum," but always, in anæmia. Then, reduced temperature, syncope, œdema, etc., are not prominent symptoms of nerve exhaustion.

Before concluding this paragraph on symptomatology, permit a reference to some zymotic, sporadic and toxic conditions, like sewer miasm, struma, leucocythenia, malaria and lead-poison, where there are so many symptoms in common that a scientific diagnosis is attainable only by the process of exclusion, or by following Micawber's plan, "to wait for something to turn up."

(*To be continued*).

—An Italian ship has been sheathed with glass plates, cast like iron plates, so as to fit the hull, to take the place of copper sheathings. The joints to the plates are made water-tight by the use of water-proof mastic. The advantages claimed for glass over copper are insensibility to oxidation and its exemption from incrustation.

Medical Societies.

THE BALTIMORE ACADEMY OF MEDICINE.

(*Continued from page* 495.)

Dr. B. B. Browne read a paper on

Traumatic Atresia of the Cervix Uteri, with Two Cases.

Obliteration of the cervical canal is due to various causes, the most frequent cause of traumatic atresia being long and difficult labors, accompanied by laceration and followed by suppuration and gangrene. Formerly when strong caustics were used more freely than at present, constriction and complete obliteration, either of the cervix or the upper part of the vagina, behind which the cervix became enclosed, frequently occurred. In the two cases which I relate the condition was caused by difficult and prolonged labor, followed by a protracted recovery.

Mary G., age 27, 13 years married, was delivered of twins 12 years ago. She was in labor three days, and had puerperal fever afterwards, and was an invalid for nearly one year. Her menses had not appeared, but she suffered with intense periodic headaches, and at times severe convulsions.

Upon examination the vagina ended in a cul-de-sac about two inches deep, which seemed to be separated from the uterus, which could be felt about one inch above. The uterus could also be clearly outlined by rectal examination.

The end of the cul-de-sac was in a line corresponding to the line of cicatricial union, and the cervix separated and dilated. A Gland glass tube was inserted into the cervical canal and a larger one in the vagina. It is a remarkable circumstance in connection with the history of atresia or absence of the vagina, even when no uterus can be found, or only a rudimentary one, incapable of performing its functions, that the artificial formation of a vagina brings considerable relief.

Mrs. Elizabeth W., of small size, aged 27, married three years, one child eighteen months ago, labor said to be very difficult, and accomplished after craniotomy; had a long and protracted recovery. Has not menstruated since, although has had the menstrual molitum.

Examination revealed a stellate laceration of the cervix and complete atresia of the uterus. The uterus was considerably enlarged.

Operation July 6. The canal, which con-

sisted of cicatricial tissue about one-half inch in thickness, was opened and about one-half a pint of thick grumous blood was discharged; the cavity was then thoroughly washed out with hot carbolized water, and the curette was also used to remove clots of the grumous mass which were adherent to the walls of the uterus.

One month later, first menstruation came on normally, and lasted three days.

In reviewing the history of these two cases it was evident that the atresia was the result of ulceration and sloughing following difficult instrumental delivery. In neither case was any treatment used to arrest the inflammatory process. The importance of thorough antiseptic vaginal irrigation in all such cases where the lochial discharges become mucopurulent and fetid, cannot be over-estimated.

DISCUSSION.

Dr. H. P. C. Wilson thinks the cessation of menstruation in apparently hearty women without any visible cause very singular. He has seen more women cease menstruating between 20 and 30 years of age than between 30 and 40.

Saw one woman, æt. 21, a picture of health, in whom the menstrual function suddenly ceased. No cause whatever could be found.

Dr. B. B. Browne said as to the opposite courses taken by his two cases after operation, he thought it could be explained by the fact that in the case in which the menstruation was not re-established, the atresia had existed for twelve years, while in the one in which the function was restored the atresia had only been present for eighteen months.

Dr. J. Edwin Michael reported a case of

Antiseptic Amputation of the Breast.

Mulatto woman, æt. 38 years, weighs 235 pounds, mother of ten children. Her breasts were in size proportionate to her weight. The growth was to the median side of the mamma; no axillary involvement. When the operation was finished, the wound measured nine inches in length. Wire sutures were used; drainage-tube laid in the wound throughout its entire length, and protruded from the most dependent angle.

Iodoform and oakum constituted the dressing.

The wound was opened for the first time on the ninth day, and everything was found to have healed; the tube had slipped into wound, and had to be dug out. There was no pus formation. At present the woman is apparently well.

Antiseptic precautions were strictly observed throughout the whole operation.

Dr. H. P. C. Wilson was strongly in favor of antiseptic precautions in all surgical procedures.

Dr. P. C. Williams has had union by first intention and complete healing of the wound by ninth day in his breast amputations, and he has never yet used antiseptics, nor drainage-tube.

Dr. J. E. Michael has also had good results without the use of antiseptics, but thinks as a rule we are safer in using them.

Dr. H. P. C. Wilson is satisfied that in this particular case, where such a large wound was necessary, had Dr. Michael avoided antiseptic precautions his result would not have been so good.

NEW YORK NEUROLOGICAL SOCIETY.

Stated meeting, March 2, 1886.

The vice-president, Leonard Weber, M. D., in the chair.

Dr. Spitzka exhibited the brain of a porpoise, demonstrating the absence of the pyramid tract in this animal, and the enormous size of the auditory nerve, which nearly equaled the lumbar cord of the same animal in transverse section. The comparatively small diameter and shortness of the segments of the lumbar cord, as compared with the dorsal segments, was dwelt upon. The brain weighed a few drachms short of 45 ounces; the animal—a bottle-nosed dolphin—weighed 236 pounds, and was obtained through Mr. Eugene Blackford.

Dr. Spitzka then presented the specimens and history of

A Case of Neurogliomatous Hypertrophy of the Pons Oblongata Transition.

The facial, pneumogastric, and hypoglossal nuclei were distinctly involved. The following was the condition of the tumor and the involved structures:

While the infiltration was diffused over a large area of the oblongata and pons, it was only in a comparatively limited compass that it could be considered as a destructive lesion. It had not advanced uniformly from a given original focus, but had extended in the direction of special tissues, which seemed to favor its progress. Thus, compact nerve-strands seemed to oppose resistance, while ganglionic tissue acted as a guide. The consequence was that the raphe, most nerve roots, and the great strands, such as the ascending root of the fifth pair and the recti-

form column, were either perfectly free or so slightly involved that it was difficult to determine whether they were affected. The vascular districts, particularly of a capillary character, which abound in the reticular field of the tegmentum, also favored the extension of the growth.

Where the lesion was at its maximum, no trace of the normal tissues could be discovered. A finely molecular basis substance, crowded with bodies resembling neuroglia nuclei, but mostly of larger size, and others resembling the small variety of ganglionic cells, but without well-defined processes, predominated over the basis substance to such an extent that even in fairly thin sections nothing but these nuclei and granules could be seen. Many of these bodies were surrounded by a halo, resembling the cell capsule hydropsia, described by Hurbich and Forel; others were imbedded in a hyaline material, presenting an appearance like that of a cell body, including a nucleus. This stained brown in alum-hæmatoxylin, while the nuclei stained a deep blue. The former were not stained by carmine.

But the most remarkable feature were the blood-vessels of the neoplasm; these, distended to their utmost capacity, abounded in at least four-fold the number and size of the opposite side when unaffected. They presented every evidence of rapid growth and enlargement, and many were evidently newly formed, while signs of vascular new formation were common. They were contorted in the most bizarre fashion imaginable, The blood within these vessels was in a condition of stasis; the vascular walls were exceedingly thin, and in many places ectatic. In several places the infiltration had undergone rarification, probably owing to softening and absorption of its hyaline products. An irregular spot of this kind was situated immediately in the concavity of the genu facialis. Another was in the corresponding situation at the head of the roots of the vagus nerve. A third in the very centre of the reticular field, of the pneumogastric rootlets. A fourth has been described as situated in the interolivary layer. In some sections the neoplasm did not cut well, and did not remain in the section, the cut surface showing the appearance usually presented by spots of malacia that have been hardened. This was the case with a spot in the very centre of a focus of the disease, which accurately corresponded to the middle abducens nerve roots.

The motor nucleus of the right trigeminus was seriously involved. Sensory nucleus of the same in the exit level slightly involved. Right lower facial nucleus destroyed. Right abducens nucleus scarcely involved. Right vagus glosso-pharyngeal nucleus nearly destroyed in higher levels, free in the lowest. Left vacoglosso-pharyngeal nucleus slightly involved in intermediate levels. Hypoglossal nucleus destroyed on both sides in its upper, on the right side in the middle third. The nuclei of the fasciculi testes cannot be identified anywhere.

Of nerve tracts, the pyramids, the transverse pons fibres, and the cerebellar peduncles with their continuations, appear to be entirely free from disease.

The posterior longitudinal fasciculi are both normal above the abducens nuclei; in that level they show slight infiltration on the right side; in the hypoglossal level the right is intensely involved. The right solitary bundle, also known as the round and trineural bundle, is greatly involved in its proper substance in the evit level of the tenth and eleventh pairs. Singularly enough, its cephalic termination in the nervus intermedius is free. The ganglionic substance in which the fascicle is imbedded is entirely destroyed in the affected levels, and the destruction extends in the direction of the afferent and efferent fibres.

The nerve rootlets are mostly normal where identifiable. In all but the most intensely affected areas they pierce the lesion without showing any signs of disease. This is notably the case with the abducens nerve. Some of the glosso-pharyngeal levels were lost. The abducens and vagus fibres, however, are distinctly less numerous on the right than on the left side. The right facial nerve, whose peripheral over-hardened portion appears normal, is the seat of intense degeneration; the axis cylinders are destroyed.

The reader thought that in the light of the post-mortem finding, deducing from the intensity of the lesion its age, and correlating it with the observed symptoms, we may infer that the neoplasm originated in the reticular field, which it involved diffusely at the start, including in its area the emerging root of the right abducens and the facial nucleus; that it extended from the latter backwards into the deep nucleus of the mixed system, and progressing towards the raphe and ventricular floor, in the transverse direction extended to the trigeminal nuclei, and to the hypoglossal nuclei and posterior longitudinal fasciculi afterwards; its latest invasion being the interolivary layer.

The gastric vagus nerve functions were the first to be involved in the thirteen months' illness; nausea and vomiting inaugurating the illness, and culminating in attacks of vertigo during the first four months of her illness; drowsiness, aggravated when the stomach was full, was a prominent symptom, and boulimia preceding death. The cardiac functions were involved seven months after the disorder first manifested itself, and became aggravated *sub finens*, as well as the dyspnœa and præcordial fears which are dependent on disturbances of the same nerve. The motor functions of the lateral set of nerves were also considerably involved. Difficulty of deglutition was experienced after four months in continually increasing severity, so that swallowing finally became impossible. The paralysis of the palate was extreme for the last six months, and had been noticed in lesser degree since the fifth month of her illness.

With the above symptoms the destructive involvement of the right vagus nucleus, the invasion of the left nucleus, and the destruction of a part of the vagus roots is in accord. The considerable involvement of the deep or motor nucleus in its upper levels, which I have proposed to term the nucleus of the pharyngeal muscles, is equally in harmony with the progress of their functional insufficiency.

Symptoms of irritation in several instances preceded the evidences of nuclear paralysis, or existed alone. Thus, spasm of the muscles of mastication preceded a slight evanescent paresis of these muscles. The motor trigeminus nucleus was involved, but not destructively so. The total paralysis of the facial nerve was preceded by facial spasm, and the last step in the extinction of the facial nerve functions, the paralysis of the uvula, was preceded by what can be interpreted in no other way than a contracture of the subsequently paralyzed half. It is an interesting fact that the stapedius paralysis which probably accounts for the tinnitus, went parallel with the paralysis of the external branches of the facial nerve, and not with the pharyngeal rami.

The subjective hemi-numbness which at no time involved the left side of the face, was a crossed symptom, in harmony with all other observations. It began four and a half months after invasion, and as it increased became associated with hemi-paresthesia, hemi-paralysis of the pressure sense, and ultimately with hemi-ataxia due to hemi-paralysis of the muscular sense. As the focus of the lesion lay in the mesal half of the reticular field, we may attribute the maximal disturbance of the weight and pressure sense to it, and the lesser disturbances, due to irritative pressure of nerve tracts, to the infiltrated but undestroyed fields near the ascending fifth root. The terminal loss of muscular sense is to be attributed to the terminal lesion of the inter-olivary layer.

The paper concluded with the following proposition: Sensory disturbance of the extremities, when existing on the side opposite to a facial nerve paralysis, if due to a single focus of disease, is as pathognomonic of a unilateral pons lesion as alternate paralysis of motion is. The difference between the two is merely one of altitude; in the former case the lesion is in the tegmental part of the pons, in the latter case in the transverse fiber mass of the pons, which, as is well known, includes the sagittal bundles of the pyramid tract.

Paralyses of associated eye movements to the side of the lesion are peculiar to the affections of the brain axis; they are, when thus situated, always due to disease of the tegmental part of the pons, and to that part of it which lies inside of the emerging root series of the fifth and seventh pairs. The inter-olivary layer and the other part of the leminiscus are to be excluded from this area, whose focus appears to be near or in the posterior longitudinal fasciculus, as well as in the neighboring reticular area and raphe, and rather cephalad of the abducens nucleus than in the same level.

That form of associated eye movement paralysis which manifests itself in inability to move the eye globes in one lateral direction in the horizontal plane can be produced by lesion situated in and cephalad to the level of the abducens nucleus. It is for this reason that absolute paralysis of the external rectus muscle of that eye which is on the side of the lesion is commonly combined with the associated movement disturbance, as in the case presented.

Nystagmic oscillation in the plane of the disturbed movement may occur in such a case, as is shown by the one to-night related. I believe that this is the first observation of the kind in which the cerebellum and transverse or cerebellar pons fibers were intact. This was not the case with Graux's patient, whose cerebellum was the primary seat of the tumor.

Dr. E. C. Seguin being requested to open the discussion, said that he thought the paper was one which was hardly open to debate, but he welcomed it as a very valuable addition to our literature of these cases.

Dr. M. A. Starr had observed in the specimens and diagrams presented an apparent implication of the acoustic nerve.

Dr. Spiztka said this nerve was entirely unaffected, and explained its seeming implication.

Dr. C. L. Dana made a brief preliminary report of a case which he thought would be interesting in connection with lesions in this region. The man, about forty-five years old, was brought into his ward with a history of having been ill a very short time. He was strong and robust-looking. He was found to have static ataxia; was unable to walk or stand. There was no motor paralysis in any of the extremities. There was anæsthesia of the temperature sense, of the tactile sense, and of the pain sense on the right side from the shoulder down, involving the right arm, right leg, and right side of the trunk; the right half of the face was not involved. There was no anæsthesia of touch, temperature, or pain sense on the left side, but in the left hand and arm there was the most marked ataxia which the speaker had ever seen. The arm showed no tremor nor paresis, but any attempt to place it in a particular position would cause it to fly about in a most senseless manner. There were some cerebral symptoms, but the intellect was clear. In a few days there developed some signs of vagus trouble; there was some difficulty in swallowing, partial paralysis of the vocal cords, inability to speak loud. The patient died after about three days from the entrance of food into the respiratory tract.

At the post-mortem examination there were found a small aneurism of the basilar artery, a recent thrombus of both vertebral arteries; near the upper aspect of the right half of the floor of the fourth ventricle was a small spot of softening. The latter lesion, it seemed to him, would account for the ataxia of the left arm. He had not yet prepared the brain further than to photograph it.

Dr. A. D. Rockwell said the difficulty in locating cerebral lesions was greater than one's reading might lead him to suppose. Out of a large number of cases of hemiplegia which he had seen, there was only one in which the symptoms were so distinct that he felt quite sure as to the location of the lesion. This occurred about a year ago, in a man whom he saw with Dr. A. W. Garman. The patient had a profound apoplectic stroke; deep coma supervened, with unconsciousness for some time. There was hemiplegia upon the right side; upon the left side there was facial paralysis. There was conjugate deviation of the eyes. The symptoms were so distinct that he ventured to locate the lesion in the lower lateral portion of the pons. The patient died within a few days, but an autopsy was not obtained.

CHICAGO MEDICAL SOCIETY.

OFFICIAL REPORT.

Stated meeting, March 1, 1886.

The president, C. T. Parkes, M. D., in the chair.

Dr. P. C. Jensen read the first paper of the evening, entitled

Digestion and Dyspepsia.

The author entered into an elaborate discussion of the physiological processes of digestion, the departure from normal, and the treatment of gastritis, ulcer of stomach, and atonic and nervous dyspepsia. Owing to the length of the paper, the author was obliged to omit a large portion of it.

Dr. J. Frank thought that in the diagnosis of stomach disease, pain under the left shoulder would not be a pathognomonic sign in case any cardiac trouble co-existed. It is well known that patients with cardiac disease complain of pain under the left shoulder. He had found that the majority of cases of dyspepsia are due to dilatation of the stomach and disease of the pancreas.

Dr. C. C. P. Silva spoke of the omission, among the cases enumerated by the paper, of that common form of indigestion due to the excessive use of tea or coffee, especially when the tea or coffee has been boiled for a long time and drank after all the aromatic principles have been evaporated, and there is left only the tannic acid, which precipitates pepsin. This is one of the most frequent causes of indigestion with ladies who abstain from cooking much, and use only tea which is not freshly made, with bread and butter, taking such a lunch frequently.

Dr. Jensen, in concluding the discussion, said that he had found that in dyspeptic, as well as heart troubles, there is pain under the left shoulder. It is a symptom of dyspepsia when other affections can be excluded. As to dilatation of the stomach, it is often a cause of dyspepsia, and he had found it especially prevalent with beer drinkers who drink beer in large quantities, ten to twenty glasses a day. As to disease of the pancreas being a cause of dyspepsia, it is a very obscure organ, and it is difficult to diagnosticate disease in it. In regard to long-drawn tea and coffee being an influential factor in the production of dyspepsia, he had observed that drink-

ing too much liquid of any kind with the food has a very deleterious effect upon the digestion; reducing the quality of the gastric secretion, and thereby hindering the proper digestion of the food.

Dr. J. H. Etheridge read a report of

Two Unique Cases of Vesico-vaginal Fistula.

In the first case the bladder appeared to be torn across from side to side about 1½ inches from the meatus urinarius, and the "flap" thus liberated was hermetically sealed to the posterior wall of the vagina. The cervix uteri was completely surrounded with adventitious connective tissue, in whose meshes was retained menstrual fluid.

In the second case, following a very protracted, severe labor, wherein the forceps had been fruitlessly used, and twelve hours later delivery was allowed to be spontaneously accomplished, the most extraordinary results ensued. *The right ovary and uterus had completely disappeared by sloughing.* The left ovary remained.

The President said he thought it a well-established fact that there is a possibility of an accidental expulsion of the uterus and its appendages occurring in connection with labor. During the past year there has been quite a discussion on the question whether it is possible for such a thing to happen; and so far as the extract published in the *British Medical Journal* goes, it seems to prove that cases do occur in which, as far as we know, no interference with forceps or otherwise was made, and yet there was extrusion of the uterus and its appendages, and sufficient constriction thereof to produce sloughing and entire loss of these organs.

Dr. F. M. Weller remembered a case in which rupture of the bladder into the vagina occurred, and the only cause to be observed was some gravel-stones found in the bladder. He had no doubt that they were the result of vesico-vaginal fistula.

Dr. R. Tilley inquired if he had asked the physicians who attended these cases if forceps were used?

Dr. Etheridge knew nothing of the antecedent histories of these patients. The first was a Bohemian woman, who spoke German indifferently, and it was difficult to get her history. The second patient was an American-born girl, and she gave a pretty succinct history of her experience. She was in labor forty-eight hours, consultation being called at the end of thirty-six. Instruments were tried but failed to deliver her, and the physicians gave it up and went home. Finally pains came on, and expulsion of the pelvic contents took place.

(*To be continued.*)

Periscope.

On a Cause of Uterine Displacement, not Hitherto Mentioned, Contraindicating the Use of Pessaries.

Dr. J. Braxton Hicks thus writes in a foreign exchange:

I write subject to correction, but I believe the cause about to be mentioned of uterine displacement and flexion has not been remarked upon, and yet it is not so very rare. Briefly stated, the concavity of the abdominal walls, noticeable in many spare women, will not permit the uterus to take its proper position in the pelvis, but, acting chiefly through the agency of the bladder more or less upon its fundus, pushes this portion back towards the promontory of the sacrum in a much more marked manner than occurs in a normal state, ending in flexion if the uterus be soft and its attachments to the front of the pelvis fairly firm. Again, if the uterus be tied by adhesions, or be already anteverted more than usual, then this condition is still more increased, and the bladder, unable wholly to rise above the uterus, expands by one arm of its Y-shaped cavity in its empty state above it, thus pressing the fundus down, and the other arm distending beneath the uterus tends to increase the anteversion, pushing up the lower end, thus increasing in two ways the anteversion; so that if the catheter be passed the fundus will be found projecting into the back of the bladder and closely opposite to the sphincter, preventing it easily entering, while it readily passes above and below to the full extent, and thus the functions of the bladder are materially interfered with. As most of these cases occur in single women, the uterus is generally held to the pubic segment of the pelvic floor fairly firmly; but in those who have been delivered the laxity of these front attachments permits the bladder to push the uterus backwards and downwards, so as to bring the back of the uterus in close contact with the anterior wall of the rectum.

In books of anatomy and obstetrics it is stated that the fundus of the uterus reaches to the level of the upper edge of the pubes. This may be taken as generally correct, though from clinical observation I should be inclined to say that it not infrequently rises a little above the plane of the conjugate. The abdominal walls, springing from the edge of the pubes, curve rather forward, and thus do not interfere with the distension of the bladder, at least not to any great extent; nor in the empty state of the bladder with the position of the uterus of normal anteversion; though when the bladder is full it retroposes the uterus towards the sacral promontory. In the condition, however, of the abdomen walls above alluded to, and described in my paper on "Abdominal Tension"*—namely, of extreme retraction—the walls become concave and are in close contact with the brim nearly throughout, in some cases resting nearly closely on the anterior surface of the iliacus and psoas, pressing to a not unimportant extent the viscera, etc. And thus it will readily be understood how that, as the bladder is being distended, unable to rise upwards, it pushes the uterus back to a degree to be measured by the difference of distance between the present incurved line of the inner surface of the walls and their former normal state. The uterus thus in course of time assumes a position with its axis approaching that of the conjugate of the middle of the pelvic cavity, the os in the retroposed position being somewhat apparently elevated, but pointing forwards, except when, to a certain extent, it becomes flexed. There is not much space between the rectum and the back of the uterus, and when fæces accumulate, as they are apt to do in this starved state of the system, they are more or less closely in contact. As I have pointed out, the pressure the walls exert is considerable—some of it due, as it apears to me, to a kind of permanent contraction of the muscles. This retraction of the walls could not take place without the absence of gas in the intestines; possibly the more solid contact of the inner face of the walls against the firm structures behind sets up a kind of chronic spasmodic state.

I am inclined to think that the uterine dartoid-like attachments are in a state of irritability also. That they are at times capable of this action I have no doubt, and this serves to explain the varying opinions of those who have seen the same case at different times, and it has its parallel in the action of the homologous dartoid tissue which causes retraction of the testicle. That all this can occur without some sort of uneasiness would be wonderful, and this it is which leads the patient to seek medical aid. Generally the patient is of a neurotic temperament, ill nourished, badly feeding, and much complaining; nor is this, perhaps, to be wondered at, seeing that owing to this incurved state and pressure the abdominal viscera are displaced and interfered with in their movements and functions, thus producing uneasiness, often visible on the face. Accordingly the medical attendant necessarily finds it a difficult task to determine whether the ailment had originated in the uterus, as a cause of reflex bad appetite and nausea, or not. If the pelvic region is much complained of, or if the medical man is overintent on uterine maladies, he would very possibly be led to examine the uterus, and, finding the organ out of place, might be led to think this the prime cause, and to attempt to correct the displacements by mechanical means. Again, if the digestive organs were most complained of, the cause of the pelvic distress might be overlooked, or attributed to ovarian irritation, or to the constipation, to neuroses, or to fancy. Supposing, then, that in the course of treatment attempts are made by the medical man to correct the position of the uterus by pessaries, the same forces which pushed the uterus into that position he will find now to resist his efforts; and although he may be able to restore the organ in part and get the pessary into place, he will find it will not—as it cannot, indeed—properly act, and that the patient, instead of being relieved, is more uncomfortable.

The same remarks apply to both conditions, whether retroversion or anteversion: so long as the abdominal walls remain in the same incurved state above described, it is difficult in most cases to elevate permanently the fundus; indeed, all attempts generally increase the distress, and the uterus shortly regains its former position. In this retracted condition of the walls, the ovaries also along with the uterus suffer from the pressure and restraint of free movement, without which none of the viscera can work painlessly and perfectly; but when pessaries are employed, these are almost certain to be brought in contact with the ovaries, and consequently much distress is felt; and this is naturally most severe when rigid pessaries are used, such as are made of vulcanite, coralline, or metal—the kinds most likely to be used in these difficult cases. In some of these cases, it is probable that the uterus was already

*Medical Society's Proceedings, 1884.

retroposed or anteposed—*i. e.*, before the retracted state of the walls occurred; but the clinical aspect of the case is the same, whatever the order of arrival. From a survey of this state of things, I think it will be conceded that the uterus has assumed the position of neutrality to the forces existing about it, and that the treatment should rather be directed to remove these abnormal forces than to drive the uterus in antagonism to them, and thus place it, as it were, between the upper and nether millstones.

Saving Condemned Limbs.

Dr. Sampson Gamgee, in the *Brit. Med. Jour.*, says:

A surgeon's responsibilities are never more delicate and weighty than when he is called upon to review a decision to amputate a limb. To the cases elsewhere published,* in which, from inability to coincide with proposed amputations, I have successfully adopted measures to save limbs, brief notes of a more recent case may be added preliminary to comment.

In compliance with an urgent call into the country, I visited a patient whose leg was to be amputated next day. I gathered from the medical attendant that a fracture through the right ankle had occurred about a fortnight previously; great swelling having supervened, a considerable number of leeches were applied, and then padded wooden splints. When these were removed, after four or five days' intense suffering, a large wound was exposed on the inner aspect of the limb, which was much swollen. Splints were then discontinued, carbolic acid lotion applied, and amputation advised after consultation with a hospital surgeon.

I found the limb from foot to knee greatly swollen and tense, of deep red color, and exquisitely sensitive to the slightest touch. The skin, to the extent of several square inches over the tendo Achillis and on the outer part of the leg, threatened disorganization; and on the inner side of the ankle was an irregularly shaped, deeply excavated wound, measuring from side to side five inches and five-eighths, from above downwards three inches and seven-eighths, and seemingly penetrating in its depressed centre into the ankle-joint. The patient's constitutional state was sound, but pain and want of sleep had produced considerable exhaustion. Unable to concur in the proposed amputation, I advised twenty-four hours' delay, to test the effect of the treatment which I proceeded to carry out. Carefully supporting the limb, I raised the foot and placed on the outer side from the lower third of the thigh downwards, a double millboard splint, gummed, and padded three inches thick with dry absorbent gauze and cotton tissue. The splint embraced the sole of the foot, which, as well as the whole inner side of the limb, was padded with equally thick and perfectly smooth folds of the tissue. The whole was now smoothly bandaged with long spirals and without reverses, and with equable but decided pressure. Four six-yard bandages were used. The limb was then placed on the outer side in a swing, and I visited the patient with the medical attendant the next day. Pain had been much less, and the loosened bandages denoted great subsidence in the swelling. Taking the limb out of the swing, the bandages on the inner aspect were cut, and the absorbent tissue, soaked with a great quantity of matter, removed; but the millboard splint on the *outer* side was not touched for some days. The skin was paler and much less sensitive and tense. The same dressing was repeated on the following three days. The improvement locally and constitutionally was then so marked that the question of amputation was not reopened; and henceforward the dressing was only renewed every other day. A considerable slough separated from over the tendo Achillis and the outer part of the leg, and the absorbent tissue before application was lightly sprinkled with some of the following lotion: Four grains of sulphate of zinc, half an ounce of methylated spirits of wine, one ounce of glycerine, and one ounce of water. The wound surface was occasionally touched with solid sulphate of copper. The dense deposit in the leg above the wound softened, and gave evidence of subcutaneous pus, which was carried off by drainage-tubes, one of which was passed several inches up the inner side of the leg, by corkscrew movement, from beneath the upper edge of the wound. Another tube was introduced through a small incision just outside the middle of the tibia. The outer ends of the drainage-tubes were made to project out of the dressings into a tin tray containing dry earth, which could be changed whenever necessary. The more perfectly to immobilize the foot and ankle, a bracket millboard splint was secured on the outer side, so as to embrace the leg just below the calf, and also the outer edge of the foot. Later on, gummed millboard splints were placed on the inner

* Case 49, p. 132, Case 51, p. 137, Case 63, p. 171, Case 84, p. 228, in Treatment of Wounds and Fractures, by the author, second edition, Churchills.

and posterior aspects; and it may give some idea of the amount of padding to state that at each dressing half a pound of the absorbent gauze and cotton tissue was used. For the first six weeks the dressing was renewed every other day, after that on Mondays and Thursdays. The patient left her bed for the couch at the end of two months; in another fortnight she removed downstairs, and then the wound on the inner side of the ankle was solidly healed, with fair and steadily improving movement in the joint.

The recovery of the limb was due to a variety of agencies, chief amongst which were immobility, position, pressure, infrequent and dry dressings, with drainage by absorbent tissue, glycerine and tubes. It was remarkable how the very tender limb, which at first could scarcely bear the slightest touch, became comfortable under equable elastic pressure, physiological position, and absolute rest. I have elsewhere* recorded a case in which a patient with a tender swollen leg, similarly treated, spontaneously expressed himself in these words: "It is wonderful how I can bear the limb handled now, and I could not stand a feather touching it last night." Glycerine in such cases acts as an antiputrescent, and by its great affinity for water powerfully aids absorbent tissues in securing perfect surface drainage, and keeping parts clean and sweet without the use of water. The plan of wound treatment, based on physiological principles, which I have enjoyed the frequent privilege of illustrating in these columns, was strikingly exemplified in the case above related. The limb was in such a condition that it was impossible to foretell its recovery with certainty, and it was only by the utmost care at every dressing that the result was attained. But I was from the first hopeful. In a large proportion of cases in hospital and private practice in which I have been called upon to amputate, I have not touched the knife and have spared the limb. A clear conception of physical and physiological principles, unprejudiced application and combination of therapeutic resources according to the circumstances of particular cases, gentle yet firm, painstaking yet not meddlesome manipulation, are very powerful agencies in saving condemned limbs.

The Causation and Treatment of Pneumonia.

Before the Academy of Medicine in Ireland, Dr. Martin read a paper on the occurrence of a large number of cases of pneumonia, within a period of three months, in a space about equal to half a square mile in the town of Portlaw. In only one instance did two cases occur in the same house, and one of these was seized while working at a place six miles distant, where he had been residing for three weeks previously, and only returned home to be nursed. No person occupied in attending on or nursing a case was affected, even under circumstances particularly favorable to such a result. In almost every instance a certain amount of unsanitary surroundings existed; and to this, aided by the particularly unfavorable climatic influence which prevailed, he attributed the outbreak—the more so that, in almost every instance, the patient stated that the illness was produced by a chill, caused by exposure when heated by exertion to the peculiarly severe easterly winds which prevailed. Of the twenty-eight cases, twenty-six recovered. The treatment was based on old-fashioned lines; in the early stage, aconite, salines, diaphoretics, poultices, leeches; and in the advanced stage, occasionally flying blisters, and, after their removal, cotton-wool covered by gutta-percha paper; the patient's strength being supported all through by milk, beef-tea, eggs, and occasionally stimulants, but in very moderate quantities. He tried quinine in some cases, and perhaps with advantage; but he preferred brandy when temperature was high, as it agreed better with the patient, and acted more speedily; but, when one considered the very unfavorable circumstances under which he had to treat these patients in their own homes—seldom clean, and amidst extreme dirt and poverty—his opinion on the action of a special drug like quinine could not be very positive or reliable.

Dr. J. W. Moore remarked that while Dr. Martin regarded the infective theory as nonproven, because, save in one instance, no two cases of pneumonia occurred in the same family, yet there was a general history of exposure to chill; and this exposure to chill has been recently advanced as one of the strongest arguments in support of the infective theory in acute pneumonia. The chill caused a certain amount of bronchial catarrh, enabling the virus of the pneumonia to find ready entrance into the system; in fact, the chill produced a traumatic condition of the bronchial mucous membrane, facilitating the entrance of the virus. The specific theory was also objected to on the ground that the disease commonly resulted from a blow or injury, rending the lung, and producing a lesion by which the virus entered the blood.

* Wounds and Fractures, page 187.

From his own observations in Cork Street Hospital, he concluded that in most cases there was an essential or true pneumonic fever; sometimes, a pythogenic pneumonia. The relation of the local lesion to the disorder seemed to be analogous to that of the lesion of Peyer's patches to the essential disorder in enteric fever. That a second case did not occur in the same house, told very little against the zymotic theory, because other people might not have been exposed to the chill.

A Case of Prolonged Rigor in an Epileptic.

Dr. J. Harrington Douty thus writes in the *Lancet:*

H. B——, aged seventy-five; epileptic since an apoplexy two years and a half ago; dementia. I was called the other day to see this patient, who was said by the charge nurse of the hospital ward to be in a rigor. The following note describes briefly the symptoms which presented themselves: She was shivering from head to foot, like one who was in the early stage of an acute febrile illness; her teeth chattered violently; the skin was pale and in a state of "cutis anserina;" her face wore an expression of distress and anxiety; she groaned at times and complained of violent pain "down the back," and said now and then in a stammering way, "Oh, so cold, so cold!" It was impossible to count her pulse or hear her heart-sounds. Respirations were 36. As each breath was drawn the shivering became more violent up to the end of inspiration; the inspiration was noisy, and ended prematurely with a jerky closure of the vocal cords; during each expiration there was a slight but distinct quieting down of the convulsions. The temperature, taken carefully in the axilla, was 98.4°. She was as conscious as she ever is, and, though in a slow stammering way, answered one's questions pretty well. The rigor went on without intermission, the spasmodic muscular contractions which constituted the shivering becoming gradually more severe, and the skin colder and of a blue tint. Twenty-five minutes from the onset of the rigor the patient became unconscious, and a violent epileptic "fit" occurred, the tonic stage of which was absent; a comatose condition followed, lasting for twenty minutes, after which the patient resumed her usual state, though, of course, she was much prostrated. The temperature throughout was at the normal.

Remarks.—Amongst the almost innumerable phenomena which usher in epileptic seizures, an aura such as this, presenting all the subjective and objective symptoms (excepting pyrexia) of an ordinary rigor would seem to be rare. In this case the stage of "contraction of the facial," which usually precedes that of the "cerebral vessels," seems to have been exaggerated; the spasm spread over the whole cutaneous vascular system, and hence the subjective "cold" and the complete rigor. It was interesting to note that the tonic stage of the fit was absent; probably the muscles were too much exhausted by the twenty-five minutes' duration of the rigor to develop any strong tonic spasm. The "fit," however, was distinctly separable from the rigor, the patient suddenly becoming unconscious, and the spasms of the rigor developing into clonic convulsions of a very severe type. The case is of some interest, too, when viewed in the light of a further testimony to the close pathological analogy between the two phenomena ordinarily distinguished by the names "rigor" and "convulsion."

Gas-forming Bacteria of the Digestive Tract.

The formation of gas in the stomach, such as occurs, for example, a short time after food, causing swelling of the organ, has never been completely explained. Though usually ascribed to fermentation, the exact nature of the process has not been discovered. Professor Miller, in a paper in the *Deutsche Medizinische Wochenschrift*, has investigated this subject. He ascribes the formation of gas in the stomach and intestines to the action of certain forms of bacteria on the carbo-hydrates of the food. These organisms have the common property of withstanding for six to eight hours the acidity of the dog's stomach, which is 0.1 per cent. greater than that of man. If a culture of the organisms be mixed with the food of the animals, diarrhœa ensues in twenty-four to thirty-six hours; and the same result Dr. Miller experienced when he took some of the culture after a meal of potatoes and bread. The symptoms were relieved by a large dose of hydrochloric acid, but he found the bacteria in the fæces for six days afterwards. In the other experiments which were performed, the organisms were added to a digestive mixture containing the food experimented upon, and a large amount of saliva. The amount of gas formed was then roughly estimated by comparing the level of the food before and after digestion. It was found that, of ordinary food, bread and potatoes gave rise to the greatest quantity of gas; while meat, fish,

and some vegetables (for example, boiled endive), gave rise to exceedingly little. Connecting these two series of facts together, Professor Miller states that, in some conditions of the alimentary tract, the organisms will give rise to flatulence, in others to diarrhœa and colic, in others, again, to both sets of symptoms combined. As an indication for the treatment of such conditions, it is evident that the antiseptic drug used must be given before meals, from which the greater part of the carbo-hydrates must be removed.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Two Annual Addresses before us treat of the general subject of the progress of medical science with uncommon force of expression and clearness of thought. One is entitled, "The Now and Then of Medicine," and is by Dr. Edward R. Mayer; the other, "What is Medicine?" by Dr. Albert L. Gihon, U. S. N.

——The Physicians' Almanac for 1886, is published by Wells, Richardson & Co., Burlington, Vt., for the purpose of introducing "lactated food" to the profession.

——In recent otological literature two interesting reprints are worthy of note. One is on Examinations of the Auditory Organs of School Children, by Dr. Friederich Rezold, of Munich, translated by Dr. Isidor Furst, of New York; and the other is on Catarrh of the Upper Air-Tract, especially in its Effects on the Ear, with Suggestions as to Treatment, by Dr. Samuel Sexton, of New York City. (Vail & Co.)

—*The Weekly Medical Review* announces that it will have a special department on Railway Surgery. We are told that the number of cases treated in the hospitals of the Missouri Pacific system alone, during one year, was over one hundred thousand, and that that system employs one hundred and forty-nine surgeons.

BOOK NOTICES.

Practical Clinical Lessons on Syphilis and the Genito-urinary Diseases. By Fessenden N. Otis, M. D. 8vo., pp. 584. Cloth. Price $2.00. New York: G. P. Putnam's Sons, 1886.

The present edition of Dr. Otis's work is in all respects the same as the previous one; as he explains in the preface, he has had a limited number of copies struck off from the plates, principally for the use of his students, and to supply the immediate orders, pending the preparation of a thoroughly revised edition upon which he is now engaged. As the profession have learned to know, and by knowing highly to esteem his treatise, we do not doubt that the revision he will give it will largely increase its future sales.

The Disorders of Menstruation. A Practical treatise by John N. Upshur, M. D. 12mo., pp. 200. Price $1.25. New York, 1886.

In a series of short chapters, the author describes the symptoms and treatment of amenorrhœa, menorrhagia, dysmenorrhœa, ovaritis, vesical irritation, pelvic cellulitis, the neuroses of menstruation, and the menopause. His style is clear, and from a wide range of reading and observation he presents the most essential features of these pathological conditions and the therapeutical methods which have proved effective. To one who wishes a small manual on this large subject, the present one can be recommended.

Von Ziemssen's Hand-book of General Therapeutics. Vol. IV. William Wood & Co., New York.

The present volume of this comprehensive work is occupied by two essays, one by Dr. Hermann Weber on the Treatment of Disease by Climate, the other on General Balneo-Therpeutics by Prof. Otto Leichtenstern.

Dr. Weber divides his subject into three parts. The first treats of the elements or factors of climate, as warmth, moisture, light, barometric pressure, and electrical conditions; the second, of the classification of climates, which he groups under the marine and inland; and third, the choice of a climate for the treatment or prevention of disease. In the latter part of the volume Prof. Leichtenstern discusses the physiological and therapeutic action of different kinds of baths and of waters when taken internally, and then proceeds to the therapeutic action of the most important groups of natural wells.

It is unnecessary to say that the review of the principles here given is thorough and most instructive. The authors are eminent teachers, and they have had the advantage of long personal acquantance with the German wells and springs where the science of Balneo-therapeutics arose; nevertheless, we cannot but regret that so little of what they say is applicable to this country without important modifications.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

THE RIGHTS OF THE AMERICAN MEDICAL ASSOCIATION.

Throughout the controversy over the International Medical Congress, we have always maintained that the American Medical Association had the unquestioned right to do with its committees, with its creatures, that which it chose to do. In a recent editorial, we strongly urged this position, and for so doing we have been taken to task by the *Medical Record* in the following language:

"We fear that our usually alert contemporary, THE MEDICAL AND SURGICAL REPORTER, does not read his exchanges. It says: 'The Association has, we maintain, the right to do just exactly that which it chooses; and when it has announced its decision, it then becomes the plain duty of all right-meaning medical men to uncomplainingly abide by this decision. The claim that the Association has not the right of arbitration has been, we say, clearly abandoned by those who at first made this claim, as is evidenced by their determination to refer the matter in dispute to the Association for arbitration.' Turning now to *The American Practitioner and News*, one of the journals which first made this claim, we read: 'The new committee pledged the Association to accept the work of the Committee on Organization. It gave the latter full power to create or destroy, to do or undo, according to what it believed would inure most to the interests of the Congress. It promised that its acts should neither be altered, nor revised, nor interfered with, in any manner whatever. It is true that such a pledge was an unusual one to give, and such a promise an unusual one to make, but both were incorporated in the bond executed by the legal representatives and accredited agents of the Association, and nothing remains for that body, when it meets in St. Louis, but to ratify the contract. This it is in honor clearly bound to do. It has absolutely no choice in the matter.'"

In reply to this criticism, we can only say that while we have great respect for *The American Practitioner and News*, yet we cannot accept its dictum as final, and we must again repeat and adhere to what we have already said, that the American Medical Association, as creator, has perfect control over that which it has created.

ILLEGAL PRACTICE.

In a recent issue we related the effort that is being made by the County Medical Society to break up the illegal practice of medi-

cine in this county, and we are glad now to be able to record the fact that the scoundrel whose case we then detailed has been sentenced to an imprisonment of six weeks; a very light sentence, it is true, but nevertheless it was a conviction and a punishment, and as this is all that the Society demands or the public requires, it is enough. There has been brought to light a law passed in 1860, part of the penal code, that makes it a criminal offence for any man, whether qualified and registered or not, to advertise special treatment for the cure of secret or venereal diseases; and under this act several men, who for years have been carrying on this nefarious practice in this city, were recently arrested. This work is being pushed with great energy, and it is a question of but a short time until the fair fame of Philadelphia's profession will be purged of its parasites.

STATE SANITARY CONVENTION.

We are informed that the State Sanitary Convention, the preliminary circular of which we noticed in a recent issue, promises to be a gathering of great practical value. Dr. William Pepper, the Provost of the University of Pennsylvania, has accepted the Presidency of the Convention; among the Vice-Presidents, we note the names of Ex-Governors, Ex-Mayors, and gentlemen distinguished in all the different walks of life. There will be representatives present from many of the different State Boards of Health, while the State Board of Maryland has signified its intention of being present in a body. A large number of subjects of vital import will be discussed, and altogether the Convention promises to be a most important affair. McCaull's Opera House, on Broad street below Locust, has been secured for the sessions of the Convention.

THE RIGHT TO EXPRESS YOUR OPINION.

Dr. Carl Seiler, of Philadelphia, has been recently subjected to a great deal of inconvenience because he saw fit some months ago, in the course of a scientific lecture before a body of scientific men, to condemn the use of a certain proprietary article, calling it by name, but using, as we understand it, this particular article as an illustration whereby to condemn the use of all proprietary articles, the constitution of which are mysteries to us.

The proprietor of this particular article felt aggrieved by this reference to his wares, and instituted a suit for slander, or libel, against Dr. Seiler.

We are happy to say that, after weary months of litigation, this suit has been decided in Dr. Seiler's favor, thus vindicating the right of freedom of speech of scientific men, who desire to protect the people from the uncertain and unknown results of secret and mysterious nostrums.

Notes and Comments.

Poisoning by Paraffin-oil.

Such cases are sufficiently rare to warrant the reproduction of the case which Dr. George Vincent publishes in the *Brit. Med. Jour.*, March 20:

He was called to a girl aged 15½ years, at 8:15 p. m., and was informed that she had taken a good drink of paraffin-oil in mistake for ginger-beer nearly an hour previously. The quantity was estimated at nearly half a pint; the girl, having put the neck of the bottle into her mouth, did not detect the mistake until she had swallowed this. After the lapse of fifteen or twenty minutes, her friends gave her some salt and water, and she vomited. The following was her condition at the time of his arrival: The surface of the body and the extremities were cold, the face pale and anxious; the pulse feeble but regular, 132 per minute; respiration sighing; and she complained bitterly of pain in the throat and in the epigastric and the left hypochondriac regions. He gave her an emetic of sulphate of zinc, and she vomited freely. He then gave her some chalk suspended in milk, whilst hot-water bottles and the bed were being prepared. The emetic was repeated, and she again vomited freely. She was now placed in bed, rolled up in blankets, and with hot water bottles to her feet and sides. She was perfectly conscious throughout. At 9 p. m. the pulse was 120, respiration sighing, temperature 98.6° Fahr. The pain was less severe. She complained of thirst and chilly sensations. At 11 p. m. reaction had thoroughly set in. The pulse was 104, stronger and fuller. The surface of the body was warm. The axillary temperature was 99.6° Fahr. Pain was less severe in the throat and left hypochondrium, but still severe in the epigastric region. The type of respiration was unaltered, and during the past two hours she had vomited several times.

She passed a restless night, being troubled with an insatiable thirst, for which she was

given milk and a solution of carbonate of magnesia, and upon which she was kept for several days, in fact, as long as the sighing respiration and the abdominal pain continued. The tonsils remained permanently enlarged, and were subsequently excised; but as she was a strumous girl, it is probable that they were enlarged before the accident.

Congenital Malformation of the Hands.

Dr. W. J. Middleton, of Steelton, Pa., reports to the *Med. Record* the following case of congenital deformity, seen in the person of a negro, now twenty-one years of age. He writes: "Each hand has a thumb and three fingers, while the middle finger is absent. The only bones lacking in the right hand are the last two phalanges of the middle finger. The proximal phalanx exists, and is of normal size, but instead of presenting in a straight line, it inclines toward the ring finger and articulates with a second phalanx common to both of these proximal phalanges. Both bones are encased in one integumentary covering, and form but one finger. The metacarpo-phalangeal articulation of the middle finger is very loose, and flexion leaves an interspace at the knuckle. The extremities of the two phalanges are not united into one bone, but are movable upon each other. The left hand lacks all the bones of the middle finger, and is cleft to the carpus. The two almost equal halves of the hand can be approximated and separated at will. The index finger of this hand has a veritable double joint at the knuckle. This joint has the usual forward flexion motion, and an almost equally perfect lateral flexion toward the ring finger. This motion results from the introduction of a sesamoid bone into the joint, a wedge-shaped bone, larger on the thumb side of the joint. The finger is as nearly straight as is usual. The man says that his parents and brothers are perfectly formed, and he knows of no reason for the deformity. His hands, notwithstanding the malformation, are large and strong. His business is to carry pig-iron from the cars at the Bessemer works."

Puerperal Insanity.

Before the Liverpool Medical Institution, Dr. J. Wiglesworth read a paper which consisted in an analysis of seventy-three recent cases of this affection, under observation in Rainhill Asylum. Puerperal insanity was looked upon as a genus of which the insanities of pregnancy, parturition, and lactation constituted the species, and the report dealt with ten cases of the first class, thirty-one of the second, and thirty-two of the third. The insanity of pregnancy was found to be the least frequent of the three varieties, and it was also the least curable; the disorder showed a tendency to develop in the later, rather than in the earlier months of gestation, and the influence of parturition was not immediately beneficial, in some cases having a contrary effect; the form of mental disorder was as often mania as melancholia. In the second variety of the disorder—the insanity of parturition—the most salient points were, that it occurred most frequently in primiparæ, and that the symptoms in the great majority of cases commenced in the first three weeks after parturition; that the form of mental disorder was more frequently mania than melancholia, and that the percentage of recoveries was high. The opinion was given that there was nothing at all peculiar in the character of the mental symptoms taken by themselves. The third variety—the insanity of lactation—presented the highest recovery rate; first lactations were not specially liable to insanity, the tendency being the other way, and the affection showed a tendency to commence in the earlier, rather than the later, months of lactation; the form of mental disorder was more frequently melancholia than mania. The prognosis was least favorable in the insanity of pregnancy, and most so in that of lactation, as shown by the following percentages:

	Pregnancy.	*Parturition.*	*Lactation.*
Recovery rate	60	74	85.7
Death rate	20	14.8	7.1
Incurable rate	20	11.1	7.1
Average duration of recovered cases	1 year.	8 4-5th mos.	7¼ mos.

Traumatic Inguinal Aneurism—Rupture of Sac—Ligature of the Common Femoral and External Iliac Arteries.

Before the Clinical Society of London (February 26), Mr. C. Mansell Moullin read a paper on this case. The patient, a slight-built man, æt. 34, had received a severe blow in the groin from the edge of a flat piece of iron about four weeks before admission. There was a good deal of swelling and discoloration about the part for some days, but this, according to his account, disappeared almost completely. Three weeks after the blow the swelling reappeared again, and continued to increase, until the morning of admission, when during some effort he was seized with violent pain and a large pulsating tumor made its appearance in the groin, extending into the scrotum and perinæum. The foot and leg were not much swollen, but

the skin in the groin was red and œdematous, and the scrotum much discolored. An incision was made into the swelling over the femoral artery (after an abdominal tourniquet had been applied), and a longitudinal slit found in the wall of the vessel, immediately under Poupart's ligament, A director was passed down it, the artery separated and tied below the injured part with catgut. A fresh incision was then made above Poupart's ligament for the purpose of securing the external iliac above the rupture. No other vessel was tied. The blood clot, some of which was old and very adherent, some quite recent, was turned out as far as possible, a large drainage-tube inserted, and the limb carefully wrapped up in cotton wool. The subsequent course was perfectly simple, except that the wound suppurated freely, and until a side opening was made, remained full of decomposing clots. The limb wasted exceedingly, and a small slough formed on the side of the heel, but the gangrenous patch was only the size of a shilling. Four months after, pulsation could just be detected in the posterior tibial and perhaps in the anterior.

Necrosis of the Lower Jaw from the Medicinal Use of Phosphorus.

Before a recent meeting of the Clinical Society of London, Mr. Hutchinson read brief notes of this case. The patient was a lady, aged 65, who was seen by Mr. Hutchinson in November last, when the whole lower half of the face was enlarged, and several sinuses opened externally. Bare discolored bone was exposed in the mouth along the whole length of the alveolus. There was also a large deposit of new shell. The discharge was profuse and fœtid in the extreme. As to the origin of the necrosis, which resembled that due to phosphorus, it was elicited from the patient that she had "been taking phosphorus for the last two years, and had quite renovated her brain thereby;" the truth being that, save for a few intervals, she had during the time named been taking three Kirby's pills daily, each containing one thirty-third of a grain of phosphorus. The condition of the patient being much reduced, operation was deferred, pending improvement in her general health, until the present month, when, after consultation with Sir James Paget, Mr. Hutchinson removed about four inches of the dead bone, without having to resort to cutting instruments, although he feared at first that this would be necessary. The patient made an excellent recovery. Mr. Hutchinson remarked that Kirby's phosphorus pills were in very extensive use, but that this was the first case that he had seen in which jaw-disease could be traced to the medical use of phosphorus. The patient had carious teeth, and inflammation of the jaw had begun in connection with one of them, and probably about six or nine months after the taking of the pills commenced.

A Unique Case.

The well-known Prof. Westphal reports the following highly interesting and unique case in the *Berl. Klin. Woch.*, 3, 1886:

A boy, æt. 12, four or five years ago suffered with scarlatina. He got well, and for four weeks remained healthy. Suddenly in the night he was seized with complete paralysis of all four extremities, and perfect immobility. The day before he is said to have complained of a peculiar sensation in his limbs, formication in the hands, and pains in the feet. While paralyzed he suffered greatly from thirst, heat, and profuse perspiration. In the beginning these attacks occurred every four to six weeks, later several times a week, and they usually lasted one day and one night, though occasionally also 48 hours. In the intervals the boy enjoyed perfect health. There is no neuropathic hereditary disposition. In the hospital, from January 7 to April 23, 1885, eight attacks were observed, which all reached their acme during the night. First, weakness of the lower, then such of the upper extremities set in; then a sharp pain attacked the legs, especially the heels; the thirst became intolerable, and the boy had a frequent desire to urinate, to which occasional inability to pass it became added. The weakness ended in complete palsy. Turning of the head, coughing, and sneezing, also became difficult. General sensation normal; feet, reflex wanting, cremaster and abdominal reflexes normal. Knee phenomenon diminished at height of seizure. Sensorium intact. For about fifteen minutes, near the acme of the attack, faradic as well as galvanic electro-muscular contractility *was completely abolished.*

Prof. Westphal shows that this unique case must not be mistaken for one of periodical paralysis as usually described. The spleen was not enlarged, there never was any regularity in the attacks, and quinine had no effect, so that latent malaria could not have been the cause. Westphal admits his inability to discover the pathogenic element and the real nature of the malady.

Pelvic Abscess Simulating Uterine Fibroid.

In this case, wherein the diagnosis of soft uterine fibroid was made, the patient was thin and anæmic. The abdomen was somewhat distended. A smooth, elastic swelling was felt rising up from the pelvis to the level of the umbilicus; it was not tender. The swelling was symmetrically situated with regard to the middle line. It was dull on percussion; laterally, beyond the limits of the swelling, the abdomen was resonant. Nothing could be heard on auscultation over the tumor. The patient was put under the influence of ether in order that the relations of the swelling might be the more thoroughly determined. Through the speculum a sanious discharge was seen to be issuing from the os externum. A catheter having been passed to make certain that the bladder was empty, a swelling was felt in front of the cervix, depressing the anterior fornix. Bimanually, this swelling was found continuous with that already noted in the hypogastric region. The uterus was movable; every upward impulse given to the cervix moved the tumor with it. The body of the uterus could not be made out distinct from the tumor. It was thought that the latter extended rather further towards the left than to the right. The sound was not used on this occasion. The temperature was 101.4° on admission, and varied for some six weeks subsequently from 102° at night (on one occasion 103.5°) to 99° in the morning. Dr. A. H. N. Lewers, who reports the case in the *Lancet*, March 6th, drew off a pint of very offensive pus by the aspirator, and the patient made a good recovery.

Application of Iodoform in Diphtheria.

Dr. A. F. Richmond writes to the *Lancet* to say that he has cured a very severe case of diphtheria by means of iodoform only. It was applied to the patches on the palate and the fauces (with a camel-hair pencil moistened with mucilage) three times a day. The child also inhaled vapor of iodoform whenever he suffered from dyspnœa, and was invariably relieved by it. The vapor was produced at the lowest possible temperature, so as not to change its chemical and curative properties. The child was unable to swallow for two days previously to being seen by Dr. Richmond, and within half an hour of the application of the iodoform he was able to take a little milk, and afterwards continued to drink with ease. The tongue became clean, and remained so. The child cut three teeth during his illness (which lasted thirteen days) and was highly salivated towards the termination of the complaint. The salivation was, however, only a little more than might take place in a perfectly healthy child when teething. There was no hyperpyrexia, and the muscular nerve-twigs were not affected; consequently he has had no paralytic symptoms, and is now in good health. Dr. Richmond has also been using iodoform with marked benefit in the treatment of various other complaints, viz., phthisis, erysipelas, herpes, burns, and scalds.

Deformed Penis.

In the *Virginia Med. Mo.*, Dr. R. H. Baylor says that he was called to visit an infant child. On reaching the house, the mother presented her child for an examination, saying, the "bottom parts were out of order." The child was two weeks old and had a very healthy look, and was as large as children at that age. Upon an examination of the privates of the child, he found a very uncommon deformity. He had never, in an active practice for thirty-five years, read of or seen a case like it. The root of the penis was attached firmly to the ossa pubis, but the body of the penis could not be seen, being deeply buried under a continuation of the abdominal skin and muscles. The scrotum was not divided into two lateral halves by the raphé, but the scrotum resembled a large bag and was sinuous. After examining the scrotum carefully, the two testes were found, and between them the penis could be distinctly felt. The glans-penis made its exit about the middle of the scrotum, between the testes. The glans-penis had its usual appearance and was covered with the prepuce, and at the apex the meatus urinarius was seen. The child passed water freely while he was making the examination. An operation will relieve the deformity.

Cyclic Albuminuria.

This condition, to which we have already called attention, is one that should be understood by all, for it will frequently happen that cases will offer, such as the one presented to Dr. Pavy (*Lancet*, March 6), where a young man, who supposed himself, and who was supposed by all about him, to be perfectly healthy, was rejected for a position because albumen was found in his urine. In this case albumen was never to be found early in the morning; about noon it was abundant, and by bed-time it was gone. The experiment of fasting was tried, without any effect, but when he remained in bed until

noon, no albumen was found. This is an important fact, the intimate nature of which Dr. Pavy does not attempt to explain. We ourselves have frequently examined urine from patients in the morning, when we would find scarcely a trace of albumen, and, in some cases, none at all, whereas that passed after an active day would be full of it. The moral of such cases is not to jump at a conclusion that a patient has organic disease of the kidney, because we find albumen in the urine.

The Pathology of Arterio-Capillary Fibroid Kidney.

Next to or even equal with the pulmonary functions, the renal functions stand foremost for the maintenance of health. If the former represents aërial respiration, the latter represents aquatic respiration. The one clears the system of gaseous, the other of solid excreta. The function of water in the body is probably not yet as much considered as it deserves to be, and our practical ideas of the circulation are too much restricted to the onward current through the capillary vessels, whilst the interstitial circulation, the transit of the blood plasma and water through the textures of the organs, is too often ignored.

Sir William Gull points out, in the April number of *The American Journal of the Medical Sciences*, that it is in the course of this interstitial circulation through the arteriole and capillary walls, that the first difficulty occurs which leads on to arterio-capillary fibroid changes, whether in the kidney or elsewhere. The changes are characteristic of a wide-spread pathology of the vascular system, supervening about the middle and later periods of life.

The Size of the Incision in Ovariotomy.

This question has been much discussed, and the size that the incision should be made is given variously by different authors. In the *Med. Press* (March 3) Dr. Lombe Atthill tell us that he has always followed the example set by Sir Spencer Wells, and made as large an opening in the abdominal wall as would enable him to see what he was doing, holding that the size of the incision does not affect the chance of recovery. Of course it should not be larger than necessary; but he holds that it is not wise to force a semi-solid tumor through a small opening, and still more so not to leave space sufficient to enable you to see clearly any bleeding point. Mr. Lawson Tait, on the other hand, insists strongly that the incision should be as small as possible, and that a large one tends to favor the formation of a hernia. We cannot agree in this. He has now been watching cases for fifteen years; several of these have had children, and others have large pendulous abdomens, but in not one has he seen a hernia to form through the line of the incision, and the fear of its occurrence will never deter him from making one sufficiently large for the object he has in view.

Case of Reproduction of Upper End of Femur after Jordan's Operation.

To a recent meeting of the Medical Society of London Mr. Edmund Owen showed a boy, aged 6, who had been admitted for long standing hip-disease on the left side. An abscess had formed in the knee of the same side, and another in the right wrist, which were both opened. The wound in the knee did badly, and the hip-mischief became more pronounced, so that ultimately it was decided to amputate at the hip by Jordan's method. The operation was successfully carried out, but in this case the periosteum was stripped from the bone and left in. At this time the boy's liver was enormously enlarged, and his urine was solid with albumen. As soon as he came round somewhat from the operation he was put on tonics, and treated to a liberal dietary, and plenty of fresh air and sunlight, and his condition rapidly improved, the liver becoming smaller and the albumen less. The result as regarded the hip was very satisfactory, bone having reformed from the periosteum, with the result of leaving a stump which would be very useful for the purposes of an artificial limb.

The Effects of Loud Sounds on the Organs of Hearing.

At the Philosophical and Medico-Chirurgical Societies of Glasgow, Dr. Barr has read papers embodying the results of his inquiries into the effects of loud sounds on the organ of hearing, in the case of boiler-makers and others who work among noisy surroundings. The facts he has brought out are only what might be expected from continuous noise acting on a delicate structure like the human ear; but the extent to which defective hearing proceeds under these abnormal conditions is brought out more fully, when we learn that the hearing-power of boiler-makers is only about 9¾ per cent., as compared with the normal standard of hearing. Dr. Barr's graphic description of the influences that bring about this state of matters in the case of the "holders-on," men who work inside of

boilers, readily explains this unfortunate result of our advanced industrial civilization. Dr. Barr suggests as a remedy for preventing this defective hearing, the wearing of an India-rubber hollow cushion or plug.

The Panacea of Modern Gynecology.

Dr. Parvin thus writes in the *Med. News:*

Winckel, in his *Lehrbuch der Frauenkrankheiten*, which has just been published, speaks of laparotomy as the panacea of modern gynecology. Such conservatism is not in correspondence with the spirit of the times when so many speak of a "Battey," or of a "Tait," as a frequent event, and regard extirpation of the ovaries, or of the tubes, or of both, as an operation the indications for which are often presented and are unequivocal. Possibly, however, the voice of conservatism ought to be heard in this, as well as in some other departments of operative gynecology. If the history of some at least of those whose sound ovaries have been removed were given months or a year or two after the extraction, it would be found that no good had resulted. Winckel regards the time as not far distant when the extirpation of the healthy ovaries for the cure of dysmenorrhœa, ovaralgia, epilepsy, hysteria, and mental disorders, will be considered in the same light as clitoridectomy, except that the latter was much more innocent and harmless.

Syphilis Transmitted by an Eustachian Catheter.

A strong man, aged 58, consulted M. Lancereaux at the Pitié Hospital in Paris for an eruption which began to appear a month ago, and eventually invaded the limbs, trunk, and head. This eruption presented the characteristic features of syphilis. The occipital and submaxillary glands were congested. The patient did not present any indication of primary syphilis. He was deaf, and had consulted an aurist on September 13th. A catheter was then passed into the Eustachian tube; the operation was repeated, when the patient's nose bled. M. Lancereaux, remembering former cases of contagion under similar circumstances, immediately recognized the possibility of contamination from the bougie. Infection must have taken place the first time the bougie was passed. On the second occasion, there was probably a chancre, which explained the bleeding from the nose.

Amblyopia and Monoplegia.

Dr. Suckling showed to a recent meeting of an English medical society a child with paralysis of the right hand, and amblyopia. Several months previously, it had been seized with vomiting, followed by Jacksonian epilepsy; the convulsions always beginning in the right hand, and then passing to the right side of the face, then to the right leg. Three months ago, the convulsions ceased to occur; but the right upper extremity remained paralyzed, and had become rigid. Latterly, the child had lost its sight, running into objects, and not recognizing its parents. The pupils responded normally, and there was no change in either fundus; there was a marked history of phthisis on the mother's side. Dr. Suckling considered that the monoplegia indicated mischief in the convolutions around the left fissure of Roland, and that the amblyopia was due to extension backwards to, and implication of the angular gyrus, and possibly, also, of the outer surface of the occipital lobe.

A Case of Multiple Myomata of the Skin, accompanied by Severe Pain.

Dr. W. A. Hardaway records, in the April number of the *American Journal of the Medical Sciences*, an interesting case which, viewed from a purely clinical standpoint, bears a strikingly close resemblance to the cases recorded by Duhring and Kosinski, which were looked upon by the authors mentioned as instances of pure neuroma of the skin. From a careful study of these cases, Dr. Hardaway feels justified in concluding that certain new growths in the skin and subcutaneous tissues, accompanied by severe pain, both of a spontaneous character, and as produced by direct irritation, may be of widely different histological structure; and that, therefore, from a clinical standpoint, we are not justified in assuming that a painful tumor or tubercle is a neuroma (fibro-neuroma) from the subjective symptoms that it presents, or from the macroscopic character of the lesions.

Partial and Sometimes General Chorea Minor from Naso-pharyngeal Reflex.

In the April number of the *American Journal of the Medical Sciences*, Dr. A. Jacobi calls attention to a form of partial or local chorea minor, affecting the muscles of the face and upper portions of the trunk, which has for its local cause an abnormal condition of the nasal and pharyngeal mucous membrane, with its influence on the terminal sensitive ends of the trifacial nerve. It is the muscles which are supplied by the terminal ends of this nerve which are first affected, but later the other muscles of the

upper extremity, and finally of the whole body, may participate in the choreic movements.

Correspondence.

Pruritus of the Anus.

Eds. Med. and Surg. Reporter:

"W. E. C." asks for suggestions for the treatment of pruritus ani. These local manifestations of disease usually owe their origin in part to derangement of the general system, and any indication in this respect should be attended to at once. If the patient's tongue is furred, he should have five grains of calomel and five grains of blue mass made into a pill once or twice a week (for a week or two), followed by a saline purgative the morning after the mercurial dose, and take for a few weeks, (with or without the addition of five drops of Fowler's solution with each dose,) the following alterative:

℞. Iodide potassium, ℥ij.
Aqua distil., ℥vj.
Fld. ext. quassia, ℥ss.
Sig.—Shake well.
Dose.—A tablespoonful after each meal.

The local treatment should be commenced by the institution of the most perfect cleanliness. The patient should be instructed to wash his anus well with a cloth and cold water after each action of the bowels, and then to bathe his anus with the following wash:

℞. Hyposulphite of soda, ʒss.
Carbolic acid, ℥ij.
Aqua distil., ℥iv.
Glycerine, ℥ij.
Mix. Sig.—Shake the wash well, and use freely after first thoroughly washing the anus with cold water.

In addition to this treatment, the patient must every night or two, after undressing for bed and washing and drying his anus, lie upon his face, and with his hands behind him, separate his nates as widely as possible, and be instructed to strain as at stool, and while thus straining the anus will protrude, and while the anus is protruding in consequence of the strong effort, five or ten grains of pulv. iodoform must be sprinkled upon the anus from a knife or spatula by an assistant. The minute eruption which causes this most distressing itching will be found most abundant at the junction of the mucous membrane of the rectum and the skin of the anus, and it is at this situation that the application does the most good. The patient should allow the iodoform to remain in the position of its application during the night, repeating during the day his ablutions of the anus after each action. The probability is that after two or three nightly applications of the iodoform all pruritus will disappear; but the patient should be directed to have the application of the iodoform continued three or four times a week until he is entirely relieved. I have never known a case to resist this treatment, and frequently washing the anus well, and nightly applying the iodoform, is the only treatment I prescribe.

News and Miscellany.

American Medical Association.

SPECIAL NOTICE.

To delegates and others who will attend the meeting of the American Medical Association, St. Louis, May 4th to 8th. Parties located east of Buffalo, Niagara Falls, Pittsburgh, and Parkersburg, will apply by mail to Secretary of Trunk Line Committee, 346 Broadway, N. Y., for certificates. Parties west of points named above and east of the Mississippi river, and north of the Ohio river, will apply to Geo. H. Daniels, Commissioner C. P. C. Chicago, Ills., for certificates. Parties south of the Ohio river, and east of the Mississippi river, will apply to M. Slaughter, Commissioner, Richmond, Va. Parties from Missouri river points, and from Chicago, will apply to E. P. Wilson, Arbitrator, Chicago. Points in the west and local points on the lines centering in St. Louis, will be arranged for by agent at starting point or upon arrival here.

Delegates in making application to the above-named persons for a certificate, must not forget to enclose a two-cent stamp to pay postage on the return letter enclosing to them the certificate. This must be done to insure the certificate being sent. Any delegate who fails, after making every effort, to get a certificate in due form, will take a receipt from the Ticket Agent at the point from which he starts, for amount of full fare paid by him, coming to the meeting; and in this receipt be particular to have named the form and number of ticket, and the road over which he will come. If not directly on one of the lines entering into this arrangement of reduced rates, pay your fare only to it, and then pay your full fare from that point, securing your certificate or receipt as above directed. State, County, or City Societies

can apply for the number of certificates they may wish, and have the number wanted sent in one envelope, instead of applying individually.

Round trip tickets from Chicago, Ills., also from New York, Richmond, Va., and Washington City, D. C., by Chesapeake and Ohio Railroad.

Members of the American Medical Association, or members of any medical societies, who may see the above, will please report it to individual members, or their societies, and try to get a notice of same in their city or county newspaper.

R. M. JORDAN, M. D.,
Chairman Transportation Committee,
St. Louis, Mo.

The Vanderbilt Clinic.

At a meeting of the trustees of the College of Physicians and Surgeons of New York recently, Dr. James W. McLane, a member of the faculty, and the physician of the late William H. Vanderbilt, announced that the four sons, Cornelius, William K., Frederick W., and George W., wished him to present to the trustees, on their behalf, the sum of $250,000 for a building in memory of their father. They contributed in equal shares to the gift. The building will be esespecially designed for the purpose of clinical instruction, a part of the sum only to be used for the structure, and the rest to be invested as an endowment fund. It is the desire of the donors to have it a charitable institution also, at which people may be treated gratuitously for any disease.

The trustees accepted the gift with pleasure. The new building will probably cost about $100,000, and will stand on the corner of Tenth avenue and Sixtieth street, on the land bought with W. H. Vanderbilt's $500,000 gift, and next to the Sloan Maternity. It will be called "The Vanderbilt Clinic." Its Board of Management will consist of Frederick W. Vanderbilt for the donors, Dr. J. C. Dalton as President of the College, Dr. W. H. Draper for the trustees, and Dr. H. B. Sands and Dr. J. W. McLane for the faculty. The new clinical buildings will form, with the other new buildings now being erected, a set of structures perfectly adapted for a medical college.

This gift makes an even million which has been given to the college since October, 1884, the date of William H. Vanderbilt's $500,000 gift. Of this $500,000, $200,000 was used in purchasing the twenty-nine lots between Fifty-ninth and Sixtieth streets on Tenth avenue, and the rest is to be expended on the new building. In January, Mr. and Mrs. Sloan will give $250,000 for the Sloan Maternity.

The work on the new building will be begun at once, and it will be completed as soon as the others. The corner-stone of the college building was laid on Saturday, April 24, by George W. Vanderbilt, and Chauncey M. Depew delivered an oration.

Professor of Anatomy in the Jefferson.

The election of a successor to Dr. W. H. Pancoast as Professor of Descriptive and Surgical Anatomy in the Jefferson Medical College has become a leading topic in medical circles, because of the failure of the trustees to make a selection at their last meeting, none of the applicants having received a majority of all of the votes cast. The applicants are: Drs. S. W. Forbes, W. W. Keen, O. H. Allis, G. W. McClellan, and J. Ewing Mears. The selection is made by the trustees in secret session from the list of applicants, and they vote by ballot. The trustees are Dr. E. B. Gardette, President; General Charles M. Prevost, Judge James R. Ludlow, James Campbell, George W. Fairman, Joseph Patterson, Joseph Allison, Furman Sheppard, D. B. Cummins, Simon Gratz, Edward H. Weil, Dr. Ellwood Wilson, B. B. Comegys, Henry C. Gibson, and Joseph B. Townsend. They were all seen recently, except Messrs. Gibson and Sheppard, who were out of the city, and Messrs. Ludlow and Gratz, who are ill, and declined to express any preference. There is no difference among the trustees that is likely to lead to any trouble over the selection of a Professor of Anatomy, and the general opinion is that a selection will be made without difficulty at the next meeting, which will be held on the 26th inst., at 8 o'clock p. m.

Water, and Plenty of It, Wanted.

A petition to Councils is in circulation, signed by men who represent the greater part of the five hundred million dollars which are invested in local industries. They ask for an abundant and certain supply of water.

The petitioners—all merchants or manufacturers—declare that they now pay a higher water rate in many parts of the city than is paid in New York, Boston, or Baltimore. They say that at present, and for years past, there has neither been enough water nor has the supply been reliable and

sufficiently free from foreign matter, thus hampering the growth of industries.

This is true, and worse than true. The remedy lies within the power of Councils. They have now the means to provide for a better water supply, and there should be no delay in getting it. The health and prosperity of the city depends on an adequate water supply. The warning raised by the manufacturers is too serious to be overlooked by Councils.

The Vagaries of an English Jury.

The verdict of acquittal in the Bartlett poisoning case, which has caused much excitement in England for several weeks past, is a curious comment on the insight of a British jury, as the case itself has been a curious comment on certain phases of British domestic life. Mrs. Bartlett expected Mr. Bartlett to die, and as she had grown to think a good deal more of her minister, Mr. Dyson, than of her husband, she concluded, with the consent of the sick husband, to treat the parson as if Mr. Bartlett were dead or did not care. So the parson and the Bartlett woman enjoyed their mutual attachment till Mr. Bartlett began to get better, when Mrs. Bartlett concluded to remove him by means of chloroform. According to common sense, Preacher Dyson and Mrs. Bartlett both ought to have been hanged; but this London jury did not think so. They will all probably join the Dilke colony and live down mere refined notions of morality.

The Burn-Brae Hospital for Mental Diseases.

This excellent institution, located a few miles from Philadelphia, has been in operation for more than a quarter of a century, and now numbers its friends in all sections of the Union. No better proof of the confidence reposed in its management by the profession and the community at large could be given, than the extensive improvements and additions that have been made during the last few years. The object of the institution is that it shall be made in every respect a home for its inmates. The location is beautiful and salubrious; the house, though possessing all the safeguards and appliances of a public hospital in external appearances and internal regulations, presents nothing forbidding or gloomy. We can speak from long personal knowledge of the confidence which may safely be placed in the management of Burn-Brae. The post-office address is Dr. R. A. Given, Clifton Heights, Delaware county, Pa.

Oleomargarine.

The Dairymen's Association of this city are proceeding to prosecute all persons found selling or manufacturing oleomargarine or any imitations of butter. This action will doubtless result in a judicial determination of the constitutionality of the law of May 21, 1885. Similar laws have been declared unconstitntional in other States, but Judge Simonton, of the Dauphin district, decided some time ago that as the act was entitled "an act for the protection of the public and to prevent adulteration of dairy products and fraud in the sale thereof," the Legislature had the constitutional power to pass such an act in the interest of the public health. The Supreme Court has not rendered any decision upon the subject, but the action of the Dairymen's Association is sure to lead to the carrying of a case to that body for final adjudication.

Atlantic City in Spring.

Dr. Boardman Reed, of Atlantic City, says of the spring season there: "Lent having begun later than usual this year, our spring business was a little late in beginning. But the hotels have never been fuller in any previous spring than they have this year since the season has been fairly open. The proprietors of all the principal houses bear testimony to this. The smaller houses, especially the boarding cottages, have not all done so well. They do not usually fill up entirely until well along in April or May. You ought to mention the important fact that Atlantic City is now the best sewered of all the New Jersey resorts.

Measles at the Prussian Court.

A dispatch from Berlin says that the epidemic of measles is spreading throughout the highest circles. The seven members of the Crown Prince's family affected by the disease have all recovered. The Prince himself furnished the severest case in his family. Other sufferers are Duke Earnest, the brother of the wife of Prince William; the Princess Charlotte, of Mecklenburg-Schwerin, and Count Olynhausen, the master of court ceremonies.

Apparent Hydrophobia.

Arthur S. Parvin, a farmer at Parvin's Mills, near Vineland, N. J., died recently, after suffering great agony for two weeks, during which he manifested all the symptoms of hydrophobia, although his disease

was supposed to be congestion of the brain. It is remembered that about a year ago he was bitten by a dog.

Artificial Cocaine.

Mr. Merck, of Darmstadt, according to a German journal, has succeeded in manufacturing cocaine from benzoyl-ecgonin, a body previously discovered by himself. He proceeds in the following manner: Several grams of benzoyl-ecgonin, with a slightly larger quantity of iodide of methyl and a little methyl alcohol, are heated in a tube to 100°. The mixture is digested in a water-bath, to expel the undecomposed iodide of methyl and methyl alcohol. From the syrupy residue cocaine is extracted as a hydriodate. From this salt, pure cocaine, dissolving at 98°—the same as natural cocaine—is produced. The artificial substance is found to answer all tests.

American Medical Association.

The special arrangements for St. Louis having been completed, those who desire to go at the reduced rates should *at once* apply to the undersigned. The entire expenses from Philadelphia and return will be $40; this includes railroad ticket, sleeper, and meals. Those who desire can stop over at Baltimore, Washington, and Cincinnati.

Wm. B. Atkinson.

The Fasting Girl of Lacrosse.

Anna Belle Langan, the nine-year-old girl who has been fasting for forty-seven days, is still strong and lively. She has an abhorrence of food, and positively refuses to eat a mouthful, even the juice of oranges. She looks comparatively well, and weighs about sixty-five pounds.

American Medical Association.

The Rush Monument Committee will meet on Monday, May 3, at 4 p. m., in the large parlor of the Lindell House, St. Louis, Mo., which will be the headquarters of the committee during the meeting of the Association.

Albert L. Gihon, M. D., *Chairman.*
Geo. H. Rohé, M. D., *Secretary.*

Personal.

—Dr. Getchell will sail for Europe on June 26, to remain till October. Mrs. Getchell and her daughter go with him.

—Sir Henry Taylor, although eighty-six years old, was in good health and took lunch with his family up to the day of his unexpected death. After that meal he remained sitting at the table after the others left the room. Presently a servant spoke to him, but received no answer, and approaching found him dead.

—Dr. Oliver Wendell Holmes will leave Boston for Europe during the present month, and will pass the summer in Europe. It is just fifty years since he last visited Europe.

Items.

—The use of calf-lymph for vaccination has been made compulsory in the Grand Duchy of Baden, from March 1.

—A gratis vaccination service has been organized at Tunis. Prizes are given to parents of children from whom vaccine can be taken.

—For *nervous vomiting*, with constipation, in a healthy girl, Prof. Bartholow directed one of the officinal pills of aloes and asafœtida, ter die.

—Herr v. Gossler, medicinalrath, has announced that from next summer students in Prussian universities must undergo instruction in vaccination with animal lymph.

—Cholera is now prevalent in Brittany, France, the nearest point to America yet reached. There have been about twenty deaths this winter,

—The demand for cocaine has, like that for bromides and chloral, extended to the general public. One drug store in New York City sells no less than six ounces each month.

—Vaccination from the calf is now practiced at four of the public vaccine stations at Calcutta; and Dr. O'Brien, the health officer, reports that it is not now regarded with disfavor by the people.

—Dr. H. J. Bigelow has declined to accept the appointment which was tendered him at the Massachusetts General Hospital as "surgeon emeritus," and also the five beds which were placed at his disposal.

—For a case of *gonorrhœal rheumatism*, Prof. Da Costa directed that blisters be appiied around the joint, and that the patient take a capsule containing ♏v, of the oil of sandal-wood, four times a day.

—Prof. Da Costa treated a case of *cerebral embolism*, causing right hemiplegia, with digitalis; to aid in restoring the collateral circulation, potassium iodide, quinine and laxatives. Result, perfect recovery.

—The Western Pennsylvania Medical College is the name chosen for the newly-organized college in Pittsburgh, Pa. We are informed that it has been liberally endowed, and will begin lectures in October next.

—Col. Waring will deliver the annual oration before the Medical and Chirurgical Faculty of Maryland, on the second day of the meeting (April 28, at 12 o'clock m.); title, "The Removal and Destruction of Organic Wastes."

—Dr. Joseph Holt, President of the Louisiana State Board of Health, has been appointed a member of the Council of the Section on Public Health and Hygiene of the next International Congress, Dr. Joseph Jones, of New Orleans, being President of the Council.

—The Society of the Alumni of the Medical Department of the University of Pennsylvania held its annual meeting March 26, in the chapel of the University. The address was delivered by Dr. Charles Gilman Smith, of Chicago. A reception to the orator followed the business session.

—Dr. M. Bertin, of Dijon, having ligated the common carotid for the cure of an "angioma," found, two years later, that a new carotid artery had formed, slightly smaller perhaps than the original, but the pulsations were distinctly visible.

—The government of Spain have information to the effect that suspicious cases of illness have occurred in the mining district of Bilbao, and that two cases have been pronounced to be cholera. A later account contains the usual denial, but it will be recollected that the disease prevailed in this locality late during the course of last autumn.

OBITUARY NOTICE.

Dr. Andrew Nebinger.

Dr. Andrew Nebinger died in this city last week at a good old age. Dr. Nebinger worthily represented the active life of the old Southwark district of this city, which even after the nominal consolidation of the city retained, and still retains, like half a dozen other districts, so much of the character of a separate community. This is not saying that Dr. Nebinger was any less a Philadelphian, or that his interests were narrow or sectional. It is simply a recognition of a very important fact, that a mere act of Assembly cannot wipe out a social organization, though it may change its political relations and lead to its ultimate absorption. In the neighborhood in which he lived Dr. Nebinger occupied a position like that of a village doctor, and a nobler position than this no man need aspire to. He was the first ma nof the community, the guide, philosopher and friend of all—a sort of patriarch, in his later days, around whom the best impulses of the neighborhood always centered. The people knew him and trusted him, and though they repeatedly rebelled against his counsel, they generally came back to him at last, when there was need to defend the interests or the honor of the ward.

Dr. Andrew Nebinger and his brother, Dr. George W. Nebinger, represented the Second ward in the Board of Education continuously for more than a quarter of a century, with the single exception of an interval of two months in 1865. At the fall election of 1864 the Republicans elected three members of the local school board in the Second ward, the Democrats electing only one. These, with the three holding over members, made the school board a tie, each party having six members. Dr. George W. Nebinger had long represented the section in the Board of Education, but partisan feeling was as strong then as now, and when the school board met the following June to elect a member of the Board of Education, six members voted for Dr. Nebinger and six voted against him. The sectional board continued balloting with the same result throughout July, August, and on up to the middle of September, when one Republican member broke the tie by voting for Dr. Nebinger.

QUERIES AND REPLIES.

Answer to the query of W. C. E., of Minn.—Wash locally night and morning with a solution of borax f 3i to a pint of hot water, with a sponge, and apply with a camel's-hair pencil continuously for three minutes the following:

℞. Sodii bicarbonat.,	3ij
Acidi carbolici,	gr. xxx.
Glycerini,	3ij.

Mix, bottle and fasten a camel's-hair pencil by means of a cork-cutter in the cork, and apply the mixture thoroughly and continuously each night and morning to the itching parts, until relief is produced.

The suggestion came from an article somewhere in the Reporter, and has been found to be entirely effective.

Very respectfully, J. W. C. O'Neal, M. D.

Gettysburg, Pa.

Dr. W., of Indiana.—1. What is the technical name of the opium habit? 2. What is its best treatment?

Ans.—The technical name is opiism, or morphiomania. For the treatment we must refer you to the various monographs on this subject.

Eds. Med. and Surg. Reporter:

Dr. W. C. E., of Minn., asks, in the issue of the Reporter for April 3, for suggestions in the treatment of obstinate "pruriuts ani." Anoint the part freely with an unguent composed of citrine ointment, 1; cosmoline, 3; then apply as much dry calomel as can be made to adhere by rubbing. Repeat this process once daily for a week, when the cure will be complete.

The same treatment is equally efficacious in "pruritus vulvæ," as well as chronic eczema, tetter, and some other cutaneous affections, although not so prompt in the latter diseases as in pruritus. The amount of citrine ointments must vary with the indications in each case.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to maintain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

RIDGE'S FOOD

FOR INFANTS AND INVALIDS.

Cereal foods are regarded by some with disfavor, as diets for infants, especially by those who maintain the dictum of chemistry in the matter as conclusive. It is urged that as they usually contain a certain amount of unconverted starch, this ingredient, owing to the absence from a baby's saliva of the solvent "*ptyalin,*" must cause indigestion and irritation in its passage through the stomach and intestines. Yet Bouchardat and Sandras have demonstrated that starch, given to animals in excess of what the saliva can act upon, has its corpuscles eroded, dissolved, and transformed into sugar, when it meets the pancreatic fluid in the duodenum. The inference is that the conversion of starch is not wholly dependent on the secretions of the buccal cavity, and that the presence of a limited quantity in an infant's food is not necessarily a source of disorder. Moreover, in dietetic questions the verdict of chemistry can only be received *cum grano salis*; and the final appeal is to practical experience; what might, could, would, or should be, under supposed conditions, loses much of its practical value, when we have easy access to what is.

The preëminent popularity of Ridge's Food has caused it to be singled out for special criticism and attack, and unsparing denunciations have been hurled at it by and on behalf of unsuccessful rivals, whose professed zeal for the welfare and protection of the innocent public would be really touching, if it did not employ the language of disappointment and defeat. Our appeal to the public for its patronage has rested on the excellence of our product; and its full justification is found at this time in an experience of thirty years, during which the sales of Ridge's Food, throughout Great Britain and her Colonies, as well as in every State in the Union, have steadily and largely increased.

Ridge's Food is made from carefully selected winter wheat which, having been reduced to an almost uniform fineness, is thoroughly cooked by a steam baking process. The nitrogenous and phosphatic elements, in which wheat is so rich, are carefully preserved, and a large proportion of the starch is converted into dextrine, while the residue undergoes a further change when the food is prepared, as directed, in the nursery, producing an article of diet at once abundantly nutritious and easily digested. Samples of the preparation will be found alittle sweet and slightly alkaline.

It is claimed for Ridge's Food that it is acceptable to the most irritable stomach of infant or invalid, when used (as sometimes it must be) without milk; and that then it is alone sufficiently nutritive to sustain life.

It is also claimed that the objections urged against the use of cereal foods in no way or degree apply to our preparation; that the consequences predicted as following such a diet for infants never occur where Ridges Food is used. So contrary, indeed, is the prediction to the results of experience, that an eminent firm of druggists in Chicago, who for many years have sold largely of our preparation write: "Its soothing and satisfying properties are so marked, as often to cause customers to inquire *it does not contain some opiate?*'

We shall be pleased to forward a sample of **RIDGE'S FOOD** to any physician not yet acquainted with it, who may favor us with their address, satisfied that, with a fair trial, we shall secure his commendation.

Lecture.

SOME POINTS ON THE HEALING OF WOUNDS.*

BY J. S. WIGHT, M. D.,

Professor of Operative and Clinical Surgery at the Long Island College (Brooklyn) Hospital.

Gentlemen: The cases which I have shown you to-day illustrate the healing of wounds—a subject always of interest to the surgeon. In the spirit that does not affirm by any master, and that does not fear the dictations of any self-constituted authority, let me bring to your attention some points of importance on the healing of wounds. But in the first place, let me say to you that the process by which wounded surfaces grow together is the healing process. And it is to this process that I invite your attention. This process has interested surgeons for all time, and it ought to interest you, who are just beginning to lay the foundations of your profession.

At the basis of this subject lie some important principles that must be understood before we can comprehend the subject itself. As we have already seen, the healing of a wound means that the several parts grow together; so that we are dealing with the subject of growth in so far as it relates to the question of repair. And we may briefly here state that the process of repair consists in the orderly proliferation of cells, which, when young and active, form granulation tissue, and which, when old and firm, form scar tissue. And this process is, after all, the substance of the healing of wounds.

*From a clinical lecture, for the Medical and Surgical Reporter.

Now, there is another principle of vital importance involved in the healing process: *When nature sets about a piece of work, it supplies an abundance of material.* This is the rule. Sometimes there is failure. Such is the case if there is not enough material. In the great majority of cases in which wounds are to be repaired, or healed, a considerable quantity of material is supplied that is not used. I could give you many significant illustrations of this important principle in other departments of knowledge. You will do well to grasp and hold this principle, for it has important practical bearings.

In the next place, let us try to understand the steps of the process of healing. The cells of the connective tissue of the wound-surface are irritated; they proliferate, forming new cells; these new cells grow together and make scar-tissue; and this scar-tissue is the bond of union between the tissues that have been severed by the wounding instrument. It is not my object now to raise the question of the proliferation of the wandering cells. My simple proposition is that the wounded surfaces grow together. And this growing together is the substance of all kinds of union; and hence, as a matter of fact, there is only one kind of union, and that is union by scar-tissue.

Now what is the nature of the differences in the process of union? It is only one of time and degree. If the surfaces of wounds grow together in a short time with slight proliferation, we call the process primary union. If the cavity of a wound is allowed to fill up with granulations, taking considerable time and being accompanied by considerable proliferation, we call the process healing by granulation. If we bring together

two granulating surfaces, so that the new cells can form scar-tissue in a short time and with but little further proliferation, we call this process secondary union. In any event we obtain union—which means that the surfaces of the wound have grown together by means of scar-tissue.

What is the one leading and elementary process going on in the surfaces of a wound? Have we not already said that it is the proliferation of cells? And have we not intimated that this proliferation is generally going on abundantly? And the surgeon expects that this proliferation will eventuate in the formation of scar-tissue. Does this always happen in the same way? Let me illustrate: A man has his foot crushed, as well as the lower part of his leg. The surgeon amputates the patient's leg in the middle third. The tissues appear healthy. In a few days excessive proliferation takes place. The flaps are separated; parts of them mortify, and abscesses form in the perijacent tissues. What has happened? The amputation may have been through tissues so much injured that they had not the power to proliferate in the normal way. There may have been the effusion of blood between the surfaces of the amputation wound. The blood-vessels of the flaps may contain an excessive quantity of coagulated blood. The perivascular spaces may be largely distended with serum. The dressings may have been so applied as to damage tissues that have been already greatly and seriously injured. *Infecting germs may have found their way to the wound surfaces. They may have proliferated, producing septic suppuration.* And this process of septic suppuration is a form of proliferation.

The great practical questions are these: How to promote the normal proliferation that eventuates in scar-tissue; how to prevent the action of those agents that interfere with this normal proliferation. For he who can make or induce scar-tissue to grow in the least possible time and with the least necessary proliferation, is no doubt the best surgeon.

How often have I seen an amputation through damaged tissues, performed with all the appliances of modern antiseptic surgery, followed by excessive proliferation, suppuration, and local mortification! And more than once in case of a crushing injury of the leg have I amputated at the knee-joint, and obtained primary union of the flaps. Now, what is the point at issue? Is it not the integrity of the cells—the cells in the continuity of the wounded surfaces? Can you compel the man with fever to climb the mountain height? Can the man with broken leg engage in pedestrian contests? Can sick and damaged cells perform the legitimate work of repair?

I once amputated the leg at the junction of the lower and middle thirds, and after securing the posterior tibial and peroneal arteries, then searched long and faithfully for the anterior tibial artery without success. When several hours had elapsed, I found the flaps distended with blood. I opened them, removed the blood, and found a small artery in an abnormal location. When this artery was tied, I sutured the flaps again, but they united in a short time by granulation. This case illustrates the importance of arresting the flow of blood.

Now, what are the precepts that we should follow? Tie the main blood vessels, as well as the muscular branches. In this work I give the preference to absorbable ligatures. And it is important to separate and pull out the artery for ligation. But how shall we arrest the oozing from the wound-surface? Two points are involved: The small blood-vessels contract and retract, and thus diminish the oozing; the thin layer of blood on the surface of the wound, in a little time coagulates, and produces contraction. I often find this point illustrated, when the blood of my patient remains on my hands for a few minutes. But then this oozing, especially after the use of the elastic bandage, does not always diminish rapidly and completely. So it is left for us to imitate the natural process—just as we do in the management of arterial hemorrhage: we apply hot water alone, or containing some astringent or antiseptic. I have often applied with a sponge both hot water and equal parts of carbolic acid and glycerine: first the carbolized glycerine, and then the water too hot for the surgeon's hand to bear with comfort. The more or less continued irrigation of the wounded surfaces—during an operation—with a warm solution of mercuric chloride will generally act promptly in arresting the oozing of blood; the strength of the solution, one to a thousand. And it is worthy of mention, that we sometimes apply the actual cautery, the electro-cautery, or the thermo-cautery, to arrest oozing, deeming the cauterized tissue more favorable to union than effused blood.

(*To be continued*).

—A porous plaster has been boycotted in Newark. The manufacturer should clap one to his backbone and stick it out.

COMMUNICATIONS.

THE VALUE OF BINIODIDE OF MERCURY AS AN ANTISEPTIC IN OBSTETRICS.—SECOND PAPER.*

BY EUGENE P. BERNARDY, M. D.

Of Philadelphia.

At a meeting held June 4, 1885, I had the pleasure of reading before this Society a paper on the "Value of Biniodide of Mercury as an Antiseptic in Obstetrics." It was with hesitancy that I brought forward the claims of a new agent whose properties were at that time comparatively unknown. My only knowledge of its effects was that which I had derived from reading the experiments of Dr. Miquel, of France, and from my experience in three cases. To-night I again bring it to your notice, not as an unknown and untried antiseptic, but as one which has proved itself far superior to any of this class of preparations which I have thus far used in obstetric practice.

Since writing my first paper, I have learned that the biniodide of mercury has been used for the past year in preference to all other antiseptics at the Lariboisière Maternité of Paris, and the reports of the results obtained have likewise been highly favorable.

In a letter written by Dr. Thomas Linn, from Paris, France, to the *Philadelphia Med. Times* (March 6, 1886), referring to the subject of antisepsis, the following passage occurs:

"Professor Panas has again something to say about antisepsis in eye surgery, principally in the treatment of cataract. The principles that guide him are, first, to make use of an antiseptic that is *sure* and *not irritating* in its action . . . Of all the antiseptics which he has used during the last two years, Dr. Panas has now definitely adopted a solution of the biniodide of mercury in 20 to 1000 ($\frac{1}{20}$ to 1000?).† Even in 40 to 1000 ($\frac{1}{40}$ to 1000?), this salt possesses a very strong anti-fermentative power, so that at double the strength nothing should resist it . . . As to the other antiseptics used: boric acid is not irritating, but its antiseptic power is doubtful; the bichloride of mercury is more irritating than the biniodide, and its antiseptic power is not half so great."

These remarks fully substantiate the opinion expressed in my former paper, that "I considered the biniodide of mercury far superior to the bichloride of mercury as an antiseptic." Of course, the cases of Dr. Panas belong to eye-surgery; but still the experiments made in both classes of cases led to the same conclusions.

I have here the history of eight other cases in which I found it necessary to use the biniodide. I have perhaps given a fuller detail of circumstances than may appear necessary. If I have so erred, I have done it for the purpose of fully and clearly showing under what conditions the antiseptic was used.

It will be observed how readily offensive odors disappeared after only a few injections of the biniodide. In some of the cases the odor around the patient was perfectly horrible.

Case 1. On September 9, 1885, I was requested to attend Mrs. F., residing at Fifty-fifth and Vine streets, in her fifth confinement. Her previous labors had taken place in Belgium, and had always been terminated by the forceps; only two children being born alive. The first and third lyings-in were complicated by attacks of puerperal fever.

I arrived about 2 p. m. Found the patient had been in labor since the previous evening (8 p. m.). On examination, found the os completely dilated, head presenting; while to the left I felt what seemed to be a prolapsed cord. The head seemed jammed between the promontory of the sacrum and the pubes. I ruptured the bag of waters so I could make a more decisive examination. Down came a loop of non-pulsating cord, which proved to be irreducible on account of the position of the head. The presentation was now made out to be a partial brow; an antero-posterior contraction existed; the promontory of the sacrum caught the side of the head and pinned it in position. I attempted to push the head up, but soon found it could not be done. I then attempted to produce flexion, but failed. Wallace's forceps met with similar results; on account of the unnatural position of the head, the forceps constantly slipped. By this time I was completely exhausted. I gave one-half grain of morphiæ sulph., which would insure the patient needed rest, as her pains had all along been active.

On my return at 5 p. m., found the condition of things the same. Dr. A. E. Roussel, who came with me, etherized the patient. I again attempted to change the position of the head, but failed. Pagot's long forceps were applied, but on the slightest traction they would slip. Tarnier's forceps seemed

*Read before the Obstetrical Society of Philadelphia, April 1, 1886.

†Evidently an error in proportion, as in the formula given, it is 1-20 gramme to the litre, or 1 to 20,000.

to grasp the head in a firmer manner, but they finally gave way. I had now worked continuously for two hours. Seeing there was no other resource, I perforated the head, and within twenty minutes the child was extracted, which weighed, without the brains, fifteen and one-half pounds.

The patient was living on the second floor, in a room partitioned off the main room of a factory. The room was well located and freely supplied with fresh air; her husband was the nurse. The next day found the pulse 100, temperature 101°; extreme tenderness over the abdomen, especially over the region of the uterus. I washed out the uterus with the $\frac{1}{1500}$ solution of the biniodide of mercury, and left orders to have it done four times a day. The second visit found the patient free from pain; pulse 80, temperature 98⅛°. Convalescence went straight on as in a normal labor. On the fourth day there was considerable pain over the uterus. Towards evening, while washing out the vagina, a clot of blood about the size of a pigeon's egg was expelled, perfectly free from odor. The patient was up on the eighth day.

Case 2. Was called (October 5, 1885,) to attend Mrs. Mc., age 30, third confinement. After an easy labor, she was delivered of twins. The placenta came away naturally, and everything went well up to the evening of the sixth day, when she became suddenly feverish and thirsty. The vaginal discharges became highly offensive, so much so that the windows had to be constantly kept opened. I immediately ordered injections (hot) of the $\frac{1}{4000}$ solution of the biniodide of mercury, asking the patient to note particularly when the odor disappeared. The first injection was followed by no effect; but on the second injection being made, the odor disappeared and remained so during convalescence. Discharged on the tenth day, well.

Case 3. On the morning of October 7, 1885, I was called to attend Mrs. B., age 28, sixth confinement. About a month previously she had called at my office, and I had given my opinion that the child she was carrying was undoubtedly dead, and that she was likely to fall in labor at any time. On my arrival at the house, found, after examination, the os perfectly dilated, and the bag of waters protruding between the vulvæ. Ruptured the bag of waters, and of all stenches, I never smelled the like. The windows had to be thrown open. On pushing my examination, found a small hydrocephalic child descending. Labor was lingering, but finally the child (in a putrid condition) was expelled naturally. The placenta came away without any trouble.

I ordered the patient to be washed out with $\frac{1}{4000}$ solution of the biniodide of mercury four times a day. The first injection I administered myself. The second and third injections were followed by a slight stinging sensation, which I believe came from using water which was too hot; but, to make certain, I reduced the biniodide to the $\frac{1}{8000}$. Within two days the discharges became perfectly odorless. Each injection was followed by a feeling of ease and comfort. Discharged well on the ninth day.

Case 4. On October 23, 1885, I was requested to attend Mrs. R. in her fourth confinement. Her third lying-in had been followed by a severe attack of puerperal fever. Upon examination, found the os rigid, dilated about an inch; waters ruptured; vertex presentation, right occipito-posterior position. Labor was lingering, os remaining somewhat rigid. About 9 p. m., finding that no headway had been made, and the patient by this time commenced showing symptoms of exhaustion, she was then fully etherized. I then applied Wallace's forceps and delivered her of a living child; no laceration. The next day she complained of pain over the region of the uterus. Ordered one-eighth grain morphiæ sulph. in tablespoonful of camphor-water every two hours. On my next visit found the tenderness had increased and the discharges from the vagina were becoming offensive. Ordered hot injections of the $\frac{1}{4000}$ solution biniodide of mercury. The following day the discharges were free from odor, the tenderness of the uterus abated. Discharged well on the fourteenth day.

Case 5. On the morning of November 3, 1885, I was asked to see Mrs. C.; first confinement. In this patient a year previously I had dilated a constricted os. Pregnancy was ushered in with marked kidney trouble; the urine yielded over thirty per cent. of albumen. The patient was enormously swollen from dropsical effusion. The case from the start was not a promising one. On arriving at the house, found the patient very nervous; on examination, found the os slightly rigid, but dilating, the waters ruptured; labor dragged on slowly all day, with very little advance. Towards twelve, midnight, she suddenly went into a spasm; I immediately etherized her; by the time she was completely etherized, Dr. Curtin, whom I had sent for, arrived. On examination the os was found dilated, slightly rigid; the ether was pushed, with the effect of softening the os. I then applied Simpson's forceps, but

they would not hold; Wallace's long forceps were applied, and in a short time the patient was delivered of a fine bouncing boy; no laceration.

The next visit found the patient doing well; pulse about 80, temperature normal. On my second visit the temperature was 102°, pulse 120–130, great fever, excessive tenderness of the uterus, the discharges very offensive. This sudden change was caused by the stupidity and incompetency of the nurse, The nurse being discharged, the mother of the patient undertook to nurse her. I immediately ordered hot injections of $\frac{1}{4000}$ solution of biniodide of mercury. The second injection the odor disappeared, but in this case did not remain away; I believe it was on account of not having a competent person to use the injections. Even as imperfectly as my orders were carried out, the biniodide held the odor under control, as the discharges were never as offensive as before its use. The patient was discharged well on the fifteenth day.

Case 6. On November 11, 1885, I attended Mrs. L., in her fifth confinement; her last two confinements had been followed by puerperal fever. She had been delivered by an excellent and careful obstetrician. She dreaded the present confinement. On arrival found the child was born; in a short time the placenta came away. The next visit found the patient doing well, with the exception of some tenderness over the uterus. Being compelled to leave the city, I handed the case over to Dr. A. E. Roussel. On his first visit, the patient was feverish, pulse 100, temperature 101°, discharges extremely offensive, excessive tenderness over the uterus. Internally, two grains of quinia and one-eighth grain morph. sulph. were ordered every three hours, and four times a day hot injections of the $\frac{1}{4000}$ solution of the biniodide of mercury. On his next visit found the patient better and the discharges free from odor. The patient was discharged on the ninth day well, feeling satisfied that the *red pills*, as she called the pellets of the biniodide, had saved her from another attack of puerperal fever.

Case 7. Mrs. B., on December 28, 1885, miscarried about the fifth month. On my arrival at the bedside, found the fœtus had been expelled early during the day; the hemorrhage had been excessive; on examination, found shreds of placenta in the vagina, could detect a larger portion in the uterus; the patient declined any interference, stating that it would come away itself. The patient lived in a small ill-ventilated house, up a court, having for nurse the neighboring women. Gave freely of ergot, but without effect; within twenty-four hours the odor from the vaginal discharges was highly offensive; ordered the $\frac{1}{4000}$ solution of the biniodide of mercury to be thrown up the vagina four times a day: a few injections readily dissipated the odor. On the fifth day the remaining portion of the placenta came away, free from odor. The patient was discharged well on the tenth day.

Case 8. On March 20, 1886, I was requested to attend Mrs. ——, wife of a physician. On my arrival at the house, found that labor pains had set in about 4 a. m. Saturday morning; examination showed the os soft and dilating, waters broken, vertex presentation; labor continued throughout the day, and terminated naturally at 10:15 p. m.; no rupture of the perineum, but the mucous membrane of the vagina, just behind the posterior fourchette, yielded to the extent of half an inch; there was a tendency to post-partum hemorrhage, which was readily checked by compression and the administration of ergot. Next day: pulse 92, skin rather hot, natural flow from the vagina. On my next visit, Monday, March 22, pulse 130, temperature 103½°, pain over the left side of the uterus; the uterus appeared flabby; not having well contracted. Same day at five o'clock, pulse 130, temperature 104°, discharges from the vagina highly offensive. Ordered the vagina to be washed out with a solution of carbolic acid (twenty per cent.), ten grains sulphate of quinine morning and night, and twenty drops of tincture of digitalis every three hours. Midnight, same day, pulse irritable, quick, and compressible; pulse 128, temperature 103°, the discharges from the vagina still offensive. Next morning, temperature and pulse the same; no change. Ordered the $\frac{1}{4000}$ solution of the biniodide of mercury to be thrown up the vagina, and if possible into the uterus; the injections were administered by the husband, and were thoroughly applied. On the 24th, the condition of the patient seemed improved; temperature 102°, pulse 115–120.

On the next morning the husband called at my house and informed me that his wife was in every way worse; the pulse was so irregular that he could not count it; temperature 104°; patient vomited several times; tendency to diarrhœa. I asked Dr. Goodell to meet me in consultation. On arriving at the bedside of the patient, found her in a remarkably good condition; pulse 100, temperature 102°; examination showed slight laceration of the mucous membrane in the

vagina, uterus was contracted; treatment to be continued, with this addition if the case did not get along well: to use ten-grain vaginal suppositories of iodoform in conjunction with the biniodide injections. These suppositories were not used, as the case from this day did well, with this exception, that on the 27th of March, or the seventh day of confinement, she was allowed to get up and use the night-vase. This was followed by a severe secondary hemorrhage, which was checked by hot-water injection and ergot. From the time the biniodide was used the vaginal discharges were free from any offensive odor, and it seemed to have a decided influence on the temperature. The patient is still under treatment.

We have here eight cases added to the three of my first paper, making in all eleven cases. This certainly gives us sufficient data to draw conclusions.

The deductions drawn from my early cases are fully sustained by my subsequent experience, and in my mind fully establish the value of the biniodide of mercury as an antiseptic in obstetric practice.

In my first series of experiments, to make my solution of the biniodide I took one and three-quarter grains of the salt, placed it in a mortar, and gradually broke up its particles, after which I slowly added one pint of boiling distilled water. This gave me a $\frac{1}{4000}$ solution. This took a long time, and often alcohol had to be added to dissolve the mercury.

Mr. J. F. Hayes, of The St. George Pharmacy, conducted a series of experiments for the purpose of placing the biniodide in the hands of the physicians in a convenient and readily-soluble form. To obtain this end, pellets were made of three different strengths. In making them sufficient iodide of potassium was added for the purpose, though not enough to cause any chemical change with the biniodide. The following is the method pursued in making the pellets. Both salts should be perfectly dry. The potassium iodide is first placed in a mortar which has been slightly warmed (just enough to take the chill out of it), and thoroughly powdered; the biniodide is then added and well mixed, but not rubbed hard, or the powder will be apt to cake. Care must be taken not to compress the pellets too hard; they keep just as well and are more easily dissolved when they are compressed just hard enough to make a firm pill. The following is the formula for the pellets:

$\frac{1}{4000}$ = mercuric iodide $3\frac{21}{25}$ grains, potassium iodide 2 grains. Mix as above, and compress in pellet.

$\frac{1}{8000}$ = mercuric iodide $1\frac{23}{25}$ grains, potassium iodide $\frac{3}{4}$ grain. Mix as above, and compress in pellet.

$\frac{1}{15000}$ = mercuric iodide $1\frac{6}{25}\frac{6}{00}$ grains, potassium iodide $\frac{1}{2}$ grain. Mix as above, and compress in pellet.

In this form the preparations can easily be carried in the satchel. When required for use, one pellet is to be added to a quart of hot water (110°). It dissolves easily, and does not stain the clothing or bedding.

The strength which I generally use is the $\frac{1}{4000}$. Should it appear too strong, the pellet can be cut in half or twice as much water used, thus giving a $\frac{1}{8000}$ strength.

221 *South 17th St., April* 1, 1886.

NEURASTHENIA.

BY C. C. THAYER, M. D.,

Of Clifton Springs, N. Y.

(*Concluded from page* 522.)

The ground of difficulty in diagnosis, one readily sees, lies in the multiplied, complex, and unclassified symptoms growing out of an unstable and irritable condition of the nervous system, reflected from the three great centres of nervous sensation, the brain, the stomach, and the genito-urinary organs, upon or through every other organ—each organ of sensory influence shading the reflection with its own peculiar nature and functions. Had neurasthenic patients only *one* organ, the symptoms would be simple and concordant—oh! how many times, in examinations, we have wished they had but one. The vaso-motor system which supplies the blood vessels, in a great degree controls the vascular *circulation*, *secretion*, and *nutrition*, and through the cerebro-spinal system, connects each organ with every other, and their nerve centres, hence the irritable heart, the irritable stomach, irritable ovary, irritable spine, irritable everything, disconcerting and obscuring discrimination till the bewildered doctor wishes his unfortunate patient where the good old deacon thought his darling, but bed-ridden wife, was so eminently fitted for.

ÆTIOLOGY.

The definition and symptoms of neurasthenia suggest at least three causes—hereditary predisposition, malnutrition, and overtaxation. Let us consider these general heads in detail:

1. Hereditary Predisposition. In this sanitarium, where are yearly gathered numerous neurasthenic patients, we find by far the greatest number from neuropathic families, where psychosis, hysteria, and other neuroses

are characteristic and historical features. Children of chronically tired and nervous parents are born tired and nervous, and henceforth too often continue in their deplorable heritage. Being born bankrupt, it matters not how you reckon, plus minus, or minus minus, the result is the same. Their weary, unstable, and restless nerves, like Noah's dove, never find rest. Accumulating but little, yet existing like the Apostle, "cast down but not destroyed," never dying, but half dead always, as Watts has it, "living at a poor dying rate." Their assets being less than their liabilities, any extra taxation throws them into nerve insolvency — hereditary nervousness producing nervous irritation, and nervous irritation producing malnutrition, and malnutrition *strengthless nerves.*

2. Malnutrition. Physical power, like physical growth, forever depends on nutrition. Innervation follows ingesta, and exhaustion malnutrition. Scrofula, syphilis, leucocythæmia, and other constitutional morbid conditions, poisoning, perverting, and preventing healthy nutrition, naturally induce nerve exhaustion. The rationale of this, according to physiology, is that *nerve force* is developed from cell nuclei; and *cell nuclei* are developed by their elective affinity for their appropriate constituents in the blood, and by a formative capacity in the blood itself; and the *blood* is produced at the expense of the organic and inorganic constituents of the food. Hence it is self-evident that in the histogenesis of cell formation, and development of nerve force, the *character and quantity of the food shapes the destiny of nerve force.*

3. Over-taxation. Contrary to the opinion of some neurologists, and the common fears of the laity, I am compelled to affirm that purely muscular taxation is far from being a common cause of neurasthenia. During three and a half years in the United States Army, a longer time among the Armenians and Mohammedans, who make long and intentionally tedious journeys to Jerusalem and Mecca, while in our hospitals, and six years in this sanitarium, I have never seen a case *originating* or *produced solely* by muscular exercise. Mental strain is a fruitful cause of neurasthenia. Yet not so much *work* as *worry*, not fidelity but friction, not the quantity but the quality—whatever produces mental irritation, irritates the sensory and motor nerves direct, and the sympathetic by reflection, and this accounts for impaired sleep, secretion, and nutrition. Neurasthenic patients come mostly from an anxious pastorate, an oppressive school system, and from business embarrassments. Grief also marks its thousands, and when it possesses the mind it ravages the system, like the mythological representation of "Mars seated in his chariot drawn by Flight and Terror; Discord goes before him in tattered garments with a torch; Anger, and Clamor, and Devastation follow."

TREATMENT.

1. Should nerve exhaustion depend upon or be associated with a hereditary cachexia, phtheiræmia, scrofula, or leucocythemia, the constitutional and hygienic methods of treatment are the most natural and the most efficient. Such patients with vitality low, formative capacity feeble, capillary circulation embarrassed, with irritable nerves, rendered more irritable by cold, require warmth and fresh air. Salt air is best for some, while mountains and woodlands better suit others. Too high altitudes are injurious, though at first stimulating at last exhausting, just as a candle shines brighter and burns faster under the same conditions. I have sent many patients with profit to the lowlands of Colorado, but none with profit to the highlands. In latitude 50 on the *highlands* of the United States, neurasthenia is most common, less so in Great Britain, still less in Germany, and still less in Asia, on the same latitude; and says Dr. Beard, it diminishes gradually as we go from this latitude towards either pole. But something more than warmth and fresh air is needed. Appropriate systematic muscular exercise is one of the best prophylactics. Windship, a feeble, consumptive youth, by strenuous and daily muscular application, not only became able to lift at one effort 2,000 pounds, but to overcome disease, and round out a goodly term of life.

2. Should the neurasthenia depend on malnutrition, attention must be paid to the food and digestion. Some eat too much; many not enough. Fitness in quality is paramount. Not the greatest amount ingested, but assimilated, is the point to be gained. Food as near as possible to nature's simplicity, either raw or cooked, without dressings and unmixed, is most easily digested and readily assimilated. This part of the treatment presents two necessities: the promotion of heat and tissue metamorphosis—oleaginous substances for their calorifying powers, and albuminous substances for their histogenetic powers—milk being their best compound representative. If there be digestive inability, an exclusive milk diet for a few weeks is best, lime-water being added to the milk not only for its antacid but styptic and reconstructive qualities. If there be acetic fermentations, starchy and saccharine

substances should be excluded and an exclusive meat diet adopted for a season. In this case all liquids should be excluded during the process of digestion. If butyric fermentation be present, meats and fats should be dropped, and the cereal grains adopted with vegetables—the *variety* at each meal small, the *quantity* sufficient.

3. Should the neurasthenia result from over-taxation, *rest* is the specific, not *recreation;* but prolonged rest of the member overtaxed. Mental rest is often promoted by *muscular exercise,* by prepossessing the thought, and by attracting the blood from the head to the muscles. I have treated successfully many patients with no other remedy than a bucksaw, saddle, fishing-rod, and gun. Where the patient is able, a light and pleasant change of business, with a little pecuniary income for condiment, is remedial.

The treatment in general of neurasthenic patients may be classed under three general heads—internal, external, and eternal.

1. We will head the list with oxygen. "Of these injurious ingredients, carbonic acid is, without doubt, the one most abundantly introduced into the nutritive fluid, and it is also the most deleterious in its effects on the system."* Oxygen is the only agent by which the system is delivered of this poison. In the systemic circulation, oxygen is exchanged for carbonic acid, and in the general circulation, carbonic acid is exchanged for oxygen. "Again, albumen is changed to fibrin in the blood in the presence of oxygen."† Hence, oxygen stands as the natural blood purifier, cell reformer, and nerve vitalizer; and this suggests fresh air, one-fifth of which is oxygen, and pure water, eight-ninths of which is oxygen. Such patients should live day and night in *free* air, and drink largely of pure water, on an empty stomach, which, indeed, they are disinclined to do.

2. The reconstructive remedies are indicated. Where there is phosphatic urine, leucocythemia, struma, etc., hypophosphites, alterative chalybeates, with light vegetable tonics; soda for the liver, potash for the kidneys, chamomile, nux and pepsin for appetite and digestion. Belladonna, ignatia and cannabis indica combined for insomnia, also Jamaica dogwood and bromidia. For external treatment a sea voyage where there is dyspepsia but not melancholy; for surface hyperæmia, with steady pulse and vaso-motor debility, a small stream of cold water on the spine striking on the last cervical vertebra for one or two minutes, followed by a brisk hand-rub; for great debility, the rest cure for three months, with an exclusive milk diet for the first two months; for aphonia, dysphagia, and spinal irritation, hot douches to the spine for one or two minutes. Oil rubs furnish warmth, nourishment, quiet, and protection. Massage furnishes exercise and magnetism. Galvanism is a restful, stimulating alterative. Faradism produces molecular motion and modification of vital processes. Franklinism I prefer for the removal of the varied "aches and pains." The electro-thermal and electro-chemical baths are efficient; the utility of electricity, however, depends upon its appropriate use, it cannot be given any way without as much harm as good. Salt rubs, acetic acid, alcohol (dilute), and quinia, are valuable.

Let us never forget, in the treatment of nerve exhaustion, that this manifestation of force in organized matter that we call life is ever dependent on and supported by the physical forces of nature—light, heat, and electricity — which, acting upon organic germs, are transformed into vital force. Light, heat, and electricity, with nature's food, nature's air, nature's exercise, and nature's rest, are nature's remedies, *par excellence,* for nerve exhaustion.

THE PHILADELPHIA NEUROLOGICAL SOCIETY.

The President, S. Weir Mitchell, M. D., in the chair.

Drs. Charles K. Mills and James Hendrie Lloyd read

Notes on the Diagnosis of Spinal Tumors.

The subjects of general and differential diagnosis of spinal tumors were alone considered; that of local diagnosis—*i. e.,* of position of the growth at different levels of the spinal axis—was deferred for another paper. The conclusions were based on a study of fifty cases, three of which were personal observations, and the remainder were collected from American, English, French, and German literature. The general diagnosis—*i. e.,* the decision as to the existence of a spinal growth—can be made from a certain train of symptoms. These are of two classes:

1. Those which are directly indicative of such a lesion.

2. Those which are corroborative.

The facts which point directly to a growth within the canal are: History of a constitutional or other cause, as of syphilis, cancer, tuberculosis, or traumatism. The onset and development are gradual and of a peculiar character. The first symptoms are those of an irritative lesion. This is probably due to the fact that tumors usually involve the membranes, as demonstrated by the cases studied. Hence, pain in the back or limbs is usually, but not always, present. The *sensory phenomena*, such as hyperæsthesia, anæsthesia, and paræsthesia, come on with more or less rapidity, with oscillating and irregular manifestations. *Motor symptoms*, such as paresis, spasm (tonic or clonic), contracture, tremor, ataxia, also manifest themselves in a similar oscillating manner. Exaggerated *reflexes* present themselves in most cases. *Trophic* and *vaso-motor disturbances* develop as the lesion progresses. These are such as wasting, ischæmia, œdema, and decubitus. *Visceral disorders*, such as paralysis of the bladder or rectum, or of their sphincters, and disorders of the heart and respiration, are, sooner or later, marked symptoms. Vomiting and gastric intestinal disorders are present in a limited number of cases. Mental disorders are present in only a very limited number of cases of tumors high in the spinal axis, but are not of diagnostic importance. Briefly stated, the phenomena which point with comparative certainty to the existence of spinal tumors are symptoms of meningeal irritation gradually increasing, and symptoms of slow compression of the cord. The data in the cases studied were somewhat meagre as to duration. The usual duration is from six months to three years.

It may be noted that fever was present at some stage in a considerable percentage of cases, but was so irregular as not to be of much diagnostic value.

The differential diagnosis of spinal tumors was considered in reference to the following affections: Spinal congestion, hemorrhage, meningitis, caries, traumatisms, sclerosis, aneurisms, neuritis, metallic and infectious disorders, and hysteria.

Spinal tumors are of constitutional or special origin, as syphilis, cancer, tuberculosis, etc.

Onset is gradual and irregular. Duration is comparatively long.

Progress is gradual, by irregular advances, toward a fatal termination.

Symptoms are inclined to be irregular, *i. e.*, unilateral or local; later, bilateral. Special symptoms, as paralysis, spasm, sensory and visceral disorders, are irregular as to time.

Decubitus and trophic changes are common late.

Reactions of degeneration are often present.

In *spinal congestion*, constitutional cause not present.

Onset is usually sudden and after exposure. Duration is short, from a few days to four months.

Disease is stationary, then retrogression of symptoms toward recovery occurs.

Symptoms are more uniformly bilateral; motor and other symptoms develop about same time.

Decubitus is rare.

Reactions of degeneration are rare.

In *spinal hemorrhages*, there is no special history, or a history of cardiac or vascular degeneration.

Onset is sudden.

Progress is more regular.

The first symptoms persist, and secondary degenerations follow, and differ according to extent and location of lesion, but are more likely to be uniformly bilateral.

In *meningitis*, the symptoms of localized compression are absent. The girdle symptom is absent. The affection is sometimes curable.

Reactions of degeneration are absent.

In *caries*, deformity is rarely absent. Rigidity of the muscles of back is a very important symptom.

In *traumatisms*, there is usually a history. The symptoms are those of caries, myelitis, meningitis, or combinations of these, according to the character of the case.

In *sclerosis*, the symptoms are usually of progressive systemic affections. Compression symptoms are absent.

Duration is longer.

Progress is gradual, and more regular.

Aneurisms are only to be distinguished when extra-spinal, causing erosion and compression.

In *neuritis*, irregular sensory, motor, and reflex disturbances are present; compression symptoms and visceral disorders being absent. It is curable.

In *metallic and infectious disorders*, a history of definite causation is present. In metallic disorders there may be special characteristic signs, such as lead-line, etc.

In *hysteria* a precedent hysterical history is usual.

Onset is often sudden. An emotional element is present. The symptoms are bilateral. Trophic changes are absent. No reactions of degeneration are present.

Dr. E. N. Brush presented

The Brain and Spinal Cord Removed that Day from a Case of General Paresis.

This case was an interesting one in connection with the question of the association of the physical and mental symptoms of paresis. In this instance physical symptoms preceded the mental by some months. In the winter of 1883–84 the patient was discovered by his physician to be ataxic; symptoms of posterior spinal sclerosis increased, and in January were associated with some mental disturbance. The patient was irritable and forgetful, but in a general way complacent. He thought his business was unusually successful, and that he possessed remarkable ability to transact business affairs. He was easily confused, and in attempting to make a short journey alone over a route with which he was perfectly familiar, lost his way, and found himself several miles from home on the wrong train.

His mental disturbance became more aggravated, and at last it became necessary to place him in a hospital. He was first placed in a private institution in a neighboring State, but there—doubtless after a slight epileptiform seizure—became so much disturbed that his removal was requested. In August last he was admitted to the Insane Department of the Pennsylvania Hospital.

On admission, his mind was markedly impaired. He was complacent, quietly submitted to suggestion, and was apparently demented. There were considerable disturbance of speech, marked tremor of tongue and lips and of upper extremities. Patellar tendon reflex abolished; pupils contracted to pinpoints and not responsive to light; Argyll-Robertson symptom was present; gait ataxic.

During his time in the hospital the patient had three epileptiform seizures, such as are met with in cases of paresis. From these he readily recovered, but with increased impairment of mental and physical powers. After two of the seizures he was aphasic for some hours.

At eight o'clock on the morning of the day of his death, the patient had a slight vertiginous attack, followed by loss of power in arms and legs to a great degree, and disturbances of the power of coördination to such an extent that he could not, except after repeated trial, direct his hand to grasp an article held up before him. He protruded his tongue, opened and closed his eyes, and did other simple things upon direction; but to everything responded "yes," and did not seem able to articulate anything else.

At 3:30 p. m. the nurse's attention was attracted by the dusky appearance of his face, which had previously been pale.

The patient was seen at once by Dr. Brush, who found his face almost cyanotic, eyes injected, pupils closely contracted. In a few minutes he had a severe convulsion. At this time the temperature was 102⅔° F. The convulsion continued, and at 4:15 the temperature was 108½° F. Death occurred at 5:45. The temperature was then 107⅖°, and the body was bathed in perspiration. An hour after death the temperature of the body was 107° F. Post-mortem rigidity came on rapidly, and at eight o'clock was very pronounced.

Examination sixteen hours after death.—The conditions found were but briefly referred to, as the speaker intends to report this and some other cases more in detail to the Society.

The skull, especially in the temporal region, was quite thin; the dura was strongly adherent to the skull, and along the median fissure to the arachnoid opia; the arachnoid was, as would be seen, thickened and opaque, over the frontal and temporal convolutions, and along the Sylvian fissures; the pia in these locations was intimately connected with the cortex, and could not be separated without tearing it or the cortex cerebri. The sections made through the brain showed marked sclerosis; indeed, sections made through the anterior convolutions gave considerable resistance to the knife. The cord in the middle dorsal region was much injected.

(*To be continued.*)

CHICAGO MEDICAL SOCIETY.

(*Continued from page* 527.)

Dr. H. P. Newman read a report of

A Case of Ruptured Ovarian Cyst, with Specimens.

Mary H., unmarried; occupation, housework; age, 25; Norwegian. Since her first menstruation at 13 years of age, the menses have been regular but scanty, accompanied by severe pain, necessitating her lying in bed the first day of each period. After coming to this country, four years ago, she seemed to suffer less in this respect, and while not strong, enjoyed a fair degree of health. In September of last year she had a mild attack of typhoid fever, convalescing at the end of the second week. During October she gained rapidly in flesh, and experienced less pain than usual at the menstrual molimen, as he afterward learned. In the second week of

November following she was taken ill with peritonitis. It was during this attack, which was of several weeks' duration in the subacute and localized form, that his attention was first called to any abnormal condition of the pelvic organs. The tenderness of the abdomen and pelvic viscera rendered a thorough exploration impossible, and it was not until January that a satisfactory examination was made.

The patient first came to his office January 25, when he found a tumor extending upward and a little to the right of the median line, from the lesser pelvic basin to midway between umbilicus and symphysis pubis, and corresponding in size and general outline to the gravid uterus at the fourth month. Further investigation revealed fluctuation in the tumor, also that it was detached from the uterus; the latter being crowded to the left and back into the hollow of the sacrum. Although the fluid contents were not examined, the growth was pronounced a probable cyst of the right ovary, and the patient so advised. To any operative procedure the patient demurred, but promised to consider the matter and report at his office the following week. Nothing was heard from her until February 3, ten days later, when he was called to her house at about 6 p. m. He found the patient up, but complaining of pain and soreness of the abdomen, which was slightly tympanitic. Temperature 99½°, pulse slightly accelerated. With the use of an opiate and hot fomentations, the following morning he found her free from pain, with less tenderness over the abdomen, and no tympanitis. Pulse and temperature normal. He enjoined rest in bed, and directed that he should be called in case of further trouble.

On the night of February 6 he was summoned by the message that the patient was very low, and not expected to live through the night. He found the patient at 11 p. m. bolstered up in a chair, in a crouching attitude, with the thighs flexed upon the abdomen. The countenance bore such a pinched and anxious expression as gave striking evidence of grave peril. He was informed that following his visit on Thursday the patient had grown quite comfortable and free from pain, and contrary to his instructions, sat up a large share of Friday. In the evening, while reading a letter, still sitting up in bed, she suddenly cried out that something had broken inside the abdomen. She suffered great distress, and was very much prostrated until 2 o'clock a. m., when she became more quiet. From this time she grew weaker, and had a very "bad feeling," as she described it, vomiting at intervals during the day, but suffering no particular pain. He was not called until late at night, twenty-four hours after the accident related. He found a rapid, feeble pulse of 140, skin moist, extremities cool, temperature 99° F., bowels tympanitic, but no pain, and little tenderness. She had passed no urine since the preceding night, and hardly a tablespoonful of dark fluid could be obtained by the catheter. A digital and bimanual examination revealed little or no change in the consistency and general outline of the tumor, as far as could be ascertained through the distended abdomen.

The gravity of the situation was explained to the friends, and an exploratory operation insisted upon as the only hope. As immediate consent could not be obtained, he advised a consultation. He therefore met Dr. A. B. Strong at ten o'clock that morning. Through the stimulants which had been freely administered during the night, the condition of the woman remained much the same. Suppression of the urine was still a marked symptom, abdominal tympanitis somewhat increased, temperature normal. The possibility of ruptured pelvic abscess, or intestinal perforation from fæcal impaction, was considered, the doctor concurring with me in urging an immediate operation. As soon as arrangements could be made the patient was etherized and placed upon a table. He requested Dr. Strong to perform the operation. The incision through the abdominal wall was about three inches in length, midway between umbilicus and pubis, in the median line. As soon as the peritoneal sac was opened there poured forth about three pints of purulent fluid. When this had been washed away, the tumor was readily recognized, filling the entire hypogastrium, its peritoneal surface engorged and discolored by the existing inflammation. Owing to the extensive adhesions, it became necessary to carry the original incision upward and through the umbilicus to a point two inches beyond, and downward to the symphisis. The fundus of the tumor was firmly attached along the under surface of the mesentery, making it necessary to ligate before removal; and, on closer inspection, a recently torn adhesion was observed, exposing a minute opening in the thinned wall of the sac, through which was oozing the purulent contents. In this connection it should be said that since her former attack of peritonitis, the patient had complained of increasing pain on resuming the recumbent posture, a fact now easily accounted for by the extent

and nature of the adhesions, which must have been thereby put upon the stretch. It is also probable that while sitting up in bed, movements of the body or abdominal viscera, together with the softening of adhesions by recent inflammation, had produced the rupture here found and so perceptible to the patient. The complete separation of the remaining adhesions, and the removal of its growth with the right ovary and fallopian tube, was accomplished. The pedicle was tied with waxed silk, the ligature cut short and left within the pelvic cavity. All torn surfaces inclined to bleed were cauterized with a hot iron. The peritoneal cavity was washed out with hot water, dried with clean sponges, the wound closed, leaving a drainage-tube in its lower angle, and the abdomen covered with antiseptic dressings.

Notwithstanding the free use of stimulants previously to the operation, and hypodermic injections of brandy toward its completion, within the next hour the woman's pulse became hardly perceptible at the wrist, and her immediate condition critical in the extreme. After the use of further injections of whisky and ammonia, and the application of bottles of hot water to the extremities, the patient rallied slightly, and recognized those about her. From nine o'clock in the evening, however, she gradually sank, and died at eleven p. m. The abdomen was opened the next morning by Dr. Strong and the writer. Though covered with recent exudations of lymph, the peritoneal surfaces were of a better color, nor had bleeding occurred from any of the points of detachment.

The tumor as here presented is a unilocular, dermoid cyst, its purulent contents (about a pint and a half) resembling very much the fluid found in the pelvic cavity. It also contained a mass of fatty substances bound together with a quantity of hair. The right fallopian tube here attached was uniformly enlarged, and held a number of drops of pus. The left ovary, which was removed post-mortem, also contained a few small cysts. The uterus was normal both in size and appearance.

The points of interest are: first, the disparity between the temperature noted and the extreme inflammatory changes in the peritoneal cavity; second, the difficulty in differentiating between rupture of this cyst and a possible pelvic abscess; also the resemblance of the symptoms to those observed in a case of twisted pedicle, as reported to the Society by our President, Dr. Parkes, at a recent meeting; and third, the liability of rupture of ovarian cysts, even of small size, where inflammation occurs, constitute additional arguments in favor of early operatian.

Dr. A. B. Strong said he believed it was generally supposed by the profession that peritonitis is always accompanied by an elevation of temperature, as indicated by the thermometer. He had recently seen a case in which a large quantity of pus was removed by section from the abdomen of a boy, in which the thermometer did not indicate any rise of temperature. These two cases seem to show that in purulent peritonitis the temperature is not always a practical aid in diagnosis, unless in a negative way.

The President was inclined to think from some of the symptoms reported that this was a case of twisted pedicle, and that the rupture was caused by the twisting of the pedicle, which is quite often the result of the subsequent distension of the cyst walls; if it is weak at any point, it ruptures. Darkness in color is one noticeable change found in twisted pedicle, and if this was not a case of twisting, there was great resemblance in the symptoms and those of cases he had seen, viz., rapid distension of the abdomen, increased temperature, symptoms of peritonitis, and suppression of urine. In case the ruptured cyst was dependent upon twisted pedicle, it might account for the separation of the adhesion which was found. The mere fact of the movement of the body which was advised against might have precipitated a turn of the tumor upon itself, which led to the rupture by a diffusion of blood. He thought it a very interesting case, and one calling attention to the necessity of insisting upon early interference in all cases where there is supposed tumor of the abdomen, accompanied by the symptoms mentioned. And where the operation is done early there is very little difference in the fatality as compared with the operation done without peritonitis being present.

Dr. Newman said, in conclusion, that he did not think twisted pedicle was present in this case. The adhesions of the upper part and sides of the tumor were of such a nature that there could be but slight twisting of the base on the pedicle, and if it had occurred as a factor in separating the adhesions it must have returned to its normal position again, for the tumor when found occupied its usual position.

Dr. Strong said he was sure the pedicle was not twisted. There were two points of attachment to the tumor, one adhering to the base of the mesentery on the right side,

the other to the sigmoid flexure, both old adhesions, and the points of attachment so located that it would be impossible for the pedicle to be twisted.

The President wished to know how the dark color was accounted for.

Dr. Strong said that it looked at first very much like a uterine tumor, being thick and vascular. It was a light mahogany color, but was not such a color as is found in a strangulated gut.

Dr. J. H. Etheridge said, in reference to the lack of correspondence between the temperature as indicated by the thermometer, and a high degree of inflammation, that the temperature will often be found in cases of peritonitis to be subnormal. In cases of gonorrhœa in the female, complicated by pelvic peritonitis, physicians are often misled by the fact that the inflammation which produces great pain in the abdomen is not accompanied by a temperature which would lead him to suppose that peritonitis is present, thus causing him to erroneously rule out the possibility of there being peritonitis.

Dr. G. W. Webster exhibited a convenient

Case of Antidotes for Poisons, with Stomach Tube.

He said that in his limited experience in the treatment of patients who had taken poison either accidentally or otherwise, he had often found it difficult to procure the proper antidotes quickly enough and in suitable form. It was this that led him to devise this case, intending at the time to have only one made for his own use. The case itself contains a pamphlet concerning poisons and their antidotes, a stomach tube, and the following drugs: ether. ammonia carbonate, nitrate of amyl, apomorphia, sulphate of atropia, brandy, camphor, animal charcoal, chloral hydrate, chloroform, digitaline, dialyzed iron, sulphate of iron, tr. of chloride of iron, mucilage, calcined magnesia, sulphate of morphia, iodide of potassium, liquor potassæ, acetate of strychnia, chloride of sodium, sulphuric acid, tannic acid, sulphate of zinc. The atropia, morphia, apomorphia, strychnia, and digitaline have been made up in compressed tablets and combined with soda, so that they can be given hypodermically.

Dr. J. Frank exhibited a specimen of

Degenerated Kidney,

with a brief history of the case. Thirteen weeks ago, lithotrity was attempted on a man sixty-nine years of age. The lithotrite broke, and the next day lithotomy was performed. The patient did well for about three weeks, when he seemed to fail again, and pus appeared in the urine. Then he got better, and the pus disappeared. But a relapse came, and he died. During the time he was voiding pus, Dr. Frank had made microscopic examinations to find casts, but was unsuccessful. There was total degeneration of the medullary substance of the kidney exhibited, while the other one was full of renal calculi.

The President remarked that the degeneration of the kidney was so great that the tube-cast formation would be impossible.

Dr. R. Tilley exhibited a sample of

Lanolin,

which he obtained through favor from Frazer & Co., of New York. He said lanolin has lately been brought prominently before the medical public by the researches of Prof. Oscar Liebreich, of Berlin, and its clinical applications by Liebreich and others. The substance exhibited, you will observe, is of a yellowish-brown color, and of a plastic consistency. The upper layer is darker than that immediately beneath. Its odor is slight, but *sui generis*. Liebreich says it should smell like wool. It is found in practically all the keratine tissues of the animal economy, but the commercial article is undoubtedly obtained from wool. The sample he supposed to be a mixture of equal parts of pure lanolin and water. Liebreich calls it a cholesterin fat, that is, a substance composed of fatty acid and cholesterin—the more commonly-recognized animal fats being, of course, compounds of fatty acids and glyrceine. He promises later to give us its exact chemical composition. The special point of interest about it to us as physicians, is, that it seems to be absorbed by the integument with much greater facility than the substances now in general use as bases for ointments. In the *Brit. Med. Jour.* of February 13, 1886, a number of formulæ are given, being so far the result of Prof. Liebreich's observations as to the most convenient method of associating it with other substances. He there refers to several clinical cases of interest, psoriasis, favus, and eczema. He regards it as an excellent base for blue ointment. He claims that when a small quantity of a sublimate ointment, 1 in 1000, made with lanolin is rubbed on the skin, in a few minutes the characteristic metallic taste of mercury appears in the mouth, and from this and other observations, concludes that all toxic agents should be used, when associated with lanolin, with great caution.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Regular meeting, January 25, 1886. The President, Daniel Lewis, M. D., in the chair.

The President announced with regard to the subject of a medical directory, referred to the Comitia Minora, that one for the county and city of New York would be issued about the first of May.

On the Advanced Treatment for Radical Cure of Hernia.

Dr. Robert Abbe read a paper with this title, in which he said of previous operations introduced for the radical cure of hernia, that if they were safe they were not effective, and consequently they had been abandoned. This might almost be said of Heaton's injection method. With regard to the open method, of which his paper treated, it was essentially the same whether performed by surgeons here or abroad. In Liverpool it was the custom to use the silver-wire suture for closing the ring, instead of catgut.

In view of the importance of the operation and the variety of results reported, he thought he should put on record a somewhat detailed history of all our operations, in order that its true merits might be judged of. For this reason the author related the histories of twenty-one cases in which he performed the open operation for the radical cure of hernia. In all of these there were urgent reasons why some operation should be performed which would offer the patient relief, giving him comfort either by effecting a radical cure or enabling him to wear a truss and to follow his vocation. According to the reports of the Liverpool surgeons, the operation was a safe one, but Dr. Abbe said the results which they had given were unusually good, and there had been in the hands of other surgeons one death in eight operations. It was true, however, that the cases operated upon were severe ones, for until the present, few others had submitted to the operation. In sixteen of Dr. Abbe's cases there was not absolute strangulation, but in all there was inabilitity to wear a truss with benefit, and to attend to business. There were three deaths. In one it was due to suppuration in varicose veins of the leg, which were operated upon at the time the open operation for hernia was performed. At the autopsy, the hernial wound and abdominal contents were in a healthy state. It was a mistake, he said, to have done the two operations at the one sitting. In another case death was due to fatty heart and to intestinal obstruction from an omental band. In the third case, death was due to hemorrhage from shrinkage of the omental tissue and loosening of the ligature. This occurred notwithstanding special precautions had been taken during the operation to avoid it. Several cases of death from hemorrhage had been reported, and Dr. Abbe thought it was due, as in his case, to a large, thick omental mass, which soon shrunk, and allowed loosening of the ligature. For this reason he advised the use of three, four, or even five ligatures or carbolized silk, and ligation of any bleeding vessels.

As to the final result of the operation, Dr. Abbe said there would in probability be a recurrence of the hernia within one or two years, if not sooner, but it was made manageable, and all of his patients had expressed great satisfaction with the relief which they had obtained. Femoral herniæ were those which caused the patients most trouble, and it was in these that the operation was most effective.

Dr. A. G. Gerster had operated in twenty-seven or more cases, in eight or nine of which herniotomy had been demanded. In three in which herniotomy had been called for, death took place, being due in one to necrosis of the returned gut, which had been thought to be viable; in another, due possibly to the same cause; and in the third, due to follicular diphtheritic inflammation. In all the cases in which herniotomy had not been called for, no disturbance followed the operation. He did not believe a radical cure was ever effected, but benefit was produced from the fact that the patient was enabled to wear a light truss and follow his vocation.

Dr. R. F. Weir had operated in eight or nine cases in which herniotomy had been called for. In two or three of these there was considerable disturbance following the operation, and he was anxious lest peritonitis should develop, but it did not. The operation he thought was useful in those cases of hernia in which a truss could not be worn, in which the inguinal ring had become much enlarged, and the patient was a sufferer or unable to attend to his business. But in milder cases, in which a light truss would control the hernia, he could not see the advantage in resorting to the open operation, which was not without risk, and which, as had been said, did not effect a radical cure, it being necessary afterward that a light truss be worn. He had not lost all faith in Heaton's injection method in light herniæ; he thought that it had resulted in a cure in his hands of from one-third to one-half of the cases.

Dr. D. A. White presented a modification of Wutzer's instrument for invaginating the inguinal canal and exciting an adhesive inflammation. Out of forty or more cases so treated, he had not had to operate twice in more than five.

Dr. P. Albert Morrow then read a paper on

The Diagnosis of Small-pox.

Dr. Gouverneur M. Smith read a report from the committeee on contagious eye disease, in which it was recommended that the state legislature be urged to pass a bill (which he read) providing for a physician attaché to institutions other than hospitals which received children. By the report it appeared that contagious eye diseases in the city institutions were alarmingly common. The report was adopted.

Dr. P. A. Morrow was elected delegate to the State Medical Society, to fill the vacancy created by the resignation of Dr. Alexander.

Editorial Department.

Periscope.

A Case in which a Gunshot Wound was Followed by Symptoms of Chronic Tetanus, which Resisted All Treatment, but Eventually Subsided after a Fall from a Donkey.

Dr. Tobin thus writes in the *Medical Press:*

Notes of this case while under treatment at Netley were published by me in the "Army Medical Reports," but its subsequent history, lately come to my knowledge, so adds to the interest of it, that I now send it forth in its entirety.

Private J. D., æt. 24. Service three years. Family and previous personal medical history good. At the action of Bronkhurst Spruit, South Africa. 20th December, 1880, he received two bullet wounds. The first was a flesh wound in the right cervico-scapular region. The second, received ten minutes later, was caused by a bullet which struck the right clavicle at the junction of the middle and outward third, fractured it, and travelled backwards. The most noticeable and immediate result of this second wound was a violent spasm of the muscles of the right arm and right side of neck, so that the arm, semi-flexed, was fixed to the side, and the head drawn down to the right shoulder at an angle of 45°. On the day after the battle the bullet which caused the first wound was removed, and a search was made for the second unsuccessfully. At a later period this search was repeated, and a general examination of the parts made under chloroform, with no result except that evidence was obtained that the neck of the scapula had been fractured by the bullet. The patient arrived at Netley in August, 1881, eight months after the receipt of the injury. His wounds had healed. He was a strong healthy man, presenting at the lower part of right side of neck a scar an inch and a half long, and another of about the same size at the junction of the middle and outer third of the right clavicle. The bone at this point was deeply grooved, and had evidently been completely fractured. The patient's right arm, flexed at a right angle, was apasmodically fixed to his side. The spasm did not extend in the same degree to the fingers and wrist, as he could move these a little. His head was drawn to the right side, from contraction of the trapezius. He suffered from constant aching pain, worse at night, in the affected parts. During the first few months of his stay at Netley, there was no perceptible change, but about the 12th of October the pain in the arm and shoulder grew worse, and the following remarkable symptoms, which represent his condition on the 16th of October, became developed. The neck and right arm were as already described. Underneath the blade of the scapula, about its centre, there was a spot painful on pressure. From this spot, at intervals of about three hours, a painful spasm extended round the front of the chest to the region of the heart, causing the patient to clutch at that organ with his hands. A few seconds later the spasmodic condition extended to the whole body ; the teeth were clenched, the masseter muscles worked violently, the eyeballs became prominent, the pupils contracted, the left arm was drawn to the side in a position similar to that in which the right was constantly fixed ; finally the muscles of the back became rigidly contracted and drew the body into a bow for about a minute, during which time the breathing almost ceased, the heart's action became tumultuous, and the face flushed. At the conclusion of each attack the patient usually tried to sit up in bed in

a dazed, exhausted condition. Throughout the symptoms gave one the idea of a tetanic spasm, and the absence of complete unconsciousness, of foaming at the mouth, and of tendency to protrude and bite the tongue, precluded the diagnosis of epilepsy. These attacks occurred every two or three hours, and lasted from five to ten minutes. The convulsions affected both sides of the body equally. There was no anæsthesia or hyperæsthesia of the surface, and no increase of temperature.

Another distressing symptom which added much to the difficulties of the case was great irritability of the stomach. This condition preceded the setting-in of the symptoms just described, and increased with them in severity. At the period I have been referring to it had reached a degree that prevented the administration of any food or medicine by the mouth. The patient, who was a very obstinate man, would not, at this time, hear of any search being made for the bullet, or of any kind of operation. It was necessary, therefore, from the 16th to the 20th of October, to feed the patient with nutrient enemata, while nitrate of amyl, chloroform, calabar bean, bromide of potassium, hydrocyanic acid, and morphia were in turn ineffectually used to try and allay the spasms. On the 20th of October he had reached a degree of exhaustion that rendered a fatal termination probable at any moment. This was explained to the patient, and he gave a reluctant consent to any operation that might be be considered necessary. In consultation it was decided to make an examination of the parts near the wound of entrance, and of the subscapular region. The patient being under the influence of ether, an incision was made parallel to, and about half an inch above the outer half of the clavicle. This passed through the upper part of the wound of entrance, and with the help of a little dissection exposed the cords of the brachial plexus, which were examined and found normal. The clavicular attachment of the trapezius was next divided, and the hand having been passed underneath the scapula, a most careful but unsuccessful search was made for the bullet in this neighborhood. Under these circumstances, and being still of opinion that the source of irritation lay somewhere about the scapula, I removed a portion of the supra-scapular and spinal accessory nerves. The supra-scapular nerve was selected for division because it partially supplied the parts in which the spasms seemed to originate, and it might, morever, have been undergoing a direct irritation in its passage through the supra-scapular notch, the bone having been fractured in that neighborhood. The spinal accessory was divided because I hoped thereby to relieve the spasm that drew the head to one side, and also to relieve the gastric irritability (his most urgent symptom), in case it was dependent on extension of irritation to the pneumogastric. The operation was followed by fairly satisfactory results. The sickness of stomach completely ceased; the head resumed its normal position and movements, the tetanic spasms were lessened in frequency from ten or twelve to two in the twenty-four hours, and the patient in a great measure regained his strength; but his arm, which was freely movable while he was under the influence of ether, became fixed in its former position as soon as the effects of the anæsthetic had passed away, and continued to occasion him much pain and weariness. In this condition he was discharged from the service with a pension, and sent to his friends in Ireland.

For some eighteen months after his discharge from Netley there was no material change in his condition. He sought relief in Mercer's Hospital, where Mr. O'Grady made a very thorough exploration of the brachial plexus, during which he found that the transverse process of one of the upper vertebræ pressed on the nerve underneath it, and that when the musculo-spiral nerve was touched, intense tetanic spasms (even while the patient was under ander an anæsthetic) were developed. A loop of silk was passed round the nerve in question so as to facilitate its division at a subsequent period should occasion require it. The patient, however, left hospital without permitting the information obtained by the exploration to be used for his benefit, and returned to his home, which is near Cootehill. Here he sought advice from Dr. Moorhead, to whom I am indebted for what I have further to relate. At the earnest request of the patient, who had had it in his head that the bullet was lodged near the shoulder-joint, Dr. Moorhead fully explored that region through an incision carried down between the deltoid and pectoralis major, but found nothing. At a point midway between the lower angle of scapula and spine, a painful spot, which gave a sense of fulness to the touch, was found, and on exploring this with a hypodermic needle a violent tetanic spasm was induced. Was the bullet here? The patient would not allow an exploratory incision to be made, and left the hospital at Cootehill with arm still fixed at side, and fits of the character already described occurring thrice daily. So he continued until Septem-

ber, 1883, when the following occurrence gave a favorable turn to his symptoms. He was thrown from a donkey and pitched on his right shoulder. A fearful shock, followed by a cessation of the fits, and later on by an almost complete restoration of the use of his arm, was the result. The position of the bullet, lodged perhaps in the spinal column, was no doubt changed by the accident.

Mycotic Endocarditis.

Dr. Wysskowitsch details the particulars of an experimental inquiry into the nature of ulcerative endocarditis (Virchow's *Archiv.*, 103, Heft 2), to which is prefixed an account of the histological examination of twelve cases of endocarditis in the human subject. Four of these cases were chronic valvular thickening with calcification and necrotic areas, surmounted by warty deposits of fibrin; in four others, the vegetations were more or less vascularized at their union with proliferated endothelial layers (thrombo-endocarditis); the ninth case appeared to be a chronic condition of the preceding; the tenth and eleventh showed post-mortem œdema after chronic endocarditis, in one case, bacteria (undoubtedly saprophytes). Lastly, there was a recent case of ulcerative endocarditis, which yielded abundance of micrococci on the valves, in the spleen and kidneys; on cultivation, the micro-organisms had the characters of staphylococcus pyogenes aureus. The experiments which form the second part of his paper consisted in inflicting on rabbits an injury of the aortic valves by means of an instrument passed down the carotid artery; then injecting into a vein a few hours later cultures of various micro-organisms. It was shown that the operation of piercing the valve was well borne, and not *per se* followed by any pathological consequences; but that the inoculation was often productive of a malignant mycotic endocarditis upon the injured valve, with secondary metastasis, as in human ulcerative endocarditis. These positive results occurred when the inoculation was made with either of the following micro-organisms: Streptococcus pyogenes, staphylococcus pyogenes aureus, and coccus sepsis (Nicolaier); but the injection of micrococcus tetragonus and bacillus pneumoniæ had no such sequel. It was also found that the staphylococcus produced much inflammatory reaction and suppuration, whereas the streptococcus, although causing much more valvular deposit and more numerous infarctions, had no such severe action. The changes in the heart and vessel were not limited to the valves pierced by the stylet; the micrococci growing also on the mitral valve and aortic wall, which happened to be eroded by the passage of the instrument. It is therefore suggested that mycotic endocarditis may be of various forms, depending upon different varieties of micro-organisms. Other experiments to induce endocarditis after inhalation and subcutaneous injection of streptococci yielded negative results; but it was found that the rabbit can only bear inhalation of very small quantities, and it was doubtful if the micro-organism entered the blood-stream at all. Professor Orth, under whose direction this research was undertaken at Gottingen, comments in another article upon the results obtained; they prove, he thinks, that the term "disposition" is no empty one, the mechanical injury of the tissue laying it open to the attacks of the micrococcus which is deposited in the clots. The experiments show also how slight may be the amount of injury required to so lower the vital resistance of the tissue.

Cerebral Syphilis; Fits; Recovery.

Dr. R. W. Burnet reports this case in the *Brit. Med. Jour.*, March 20:

The patient, a man aged 33, was admitted into the Great Northern Central Hospital on September 30, 1885, complaining of "fits," and of severe pains in the head. There was no special wasting of the muscles, but his grasp with the left hand was comparatively feeble; his pupils reacted to light, and there was no squint. The lungs were free, but there was a systolic *bruit* heard in the third left interspace. The left arm and leg were colder than the right; muscular sense and cutaneous sensibility were deficient on the left side. Patellar reflex was exaggerated; there was no ankle-clonus. Smell and taste were unimpaired; but hearing was defective in the left ear. Sight was fairly good. Mr. Marcus Gunn examined the eyes, and reported that the eyeballs appeared normal; the left pupil was larger than the right; both acted to light, and with convergence, but the left was always larger. The papilla in the right eye was greatly swollen, and its boundaries obliterated; in its vicinity several flame-shaped hemorrhages and white patches were seen; the veins were greatly distended; the arteries were much occluded. The left eye was in much the same condition, but the swelling was less. The patient stated that seventeen years ago he had venereal sore with some urethral dis-

charge, and swelling of glands in the groin, without suppuration. There was no history of rash, sore throat, or other symptoms. About thirteen months before his admission he was suddenly seized, while at work, with a fit; and he had the fits very frequently, sometimes daily, since that time. The fits began with slight twitching of the extensor muscles of the forearm or leg, and slight jumping of the hand or foot, or both—but always on the left side. The spasms increased, till the whole left side, including the face, was in a state of clonic spasm. The forearm was flexed on the arm, and the wrist on the forearm; the fingers were flexed, but the first was not clenched. The leg remained extended, and the spasms were limited to the front of the thigh and the leg. After a fit, the affected parts were left cold and paralyzed. This had lasted two hours, and sometimes days had elapsed before he had much control over the left foot. The man had been treated as an out-patient, with bromide and iodide of potassium, but without effect. During the first week after his admission he had nine fits. He was ordered mercurial inunction, and iodide of potassium in seven-grain doses. After October 6, he had no more fits, and very much less twitching. He improved in general health, and gained weight. On November 2, the swelling of the papilla was much less, and the white patches had nearly disappeared. On November 3, he was made an out-patient. He still attended, and was taking from ten to fifteen grains of iodide of potassium three times daily. He could read with ease, and had no fits, but had still occasional twitchings.

A Foreign Body in the Eyeball Removed by Means of a Magnet.

Dr. A. G. Hobbs thus writes in the *Southern Medical Record:*

Mr. A. W., of Alabama, aged forty-two, while drilling with a steel drill, received a wound in the right eye, which gave him but little pain at first, but after twenty-four hours the pain became severe. His physician, Dr. A. B. Coleman, saw him on the evening of the day the injury occurred, and was sure he could see the piece of steel (looking at it, according to the patient's account, with an ophthalmoscope), but would not attempt to extract it. The eye was at once atropinized, but, on the third day, the pain, photophobia, and congestion had increased so much that the doctor referred him to me. I saw him on the fifth day, when I found a small opacity at the sclero-corneal junction, the point of entrance of the piece of steel. I also found considerable iritis, with inflammatory effusions, in the ciliary region. The effusion was so great that his vision was reduced to "finger counting," and it was impossible for me to see beyond the iris. Knowing that the good eye was in danger of becoming involved, through sympathy, I determined to try the magnet, though I had but little idea of the locality of the foreign body.

After thoroughly cocainizing the eye, I introduced a Graefe's knife through the cornea and ciliary region, into the vitreous, following the course of the steel as near as possible, and just missing the lens. After the hemorrhage had ceased, I gently introduced the probe of a Gruning's magnet, and slowly withdrew it, till, upon the fifth withdrawal, a small, irregular piece of steel, about half the size of the head of a pin, came out, adhering to the point of the probe. There was but little loss of vitreous, a very small bead only following the fourth and fifth withdrawals of the probe. The eye was at once firmly bandaged, the patient placed at rest, and the case treated as an ordinary traumatism of the ciliary region.

The pain and inflammation gradually subsided under treatment, and the inflammatory exudations were slowly absorbed till his vision, at the end of three weeks, was $\frac{6}{x\ x}$. Two weeks later vision remained the same, but all symptoms had subsided, except a small band of iritic adhesions in the region of the wound, which left the pupil irregular in shape. I have no doubt that, had the magnet not been successfully used in this case, an enucleation would have been necessary. I expected that a traumatic cataract would be the result, but I have not heard that such has been the case. I infer that the vision still remains as good, if it has not improved, since the acute symptoms passed away.

The Therapeutic Use of the Digestive Ferments.

Before the Academy of Medicine in Ireland, Dr. Purser read a paper on the Therapeutic Uses of the Digestive Ferments, in which he condemned as useless and irrational the internal administration of these substances, and argued that their true use in medicine was limited to the preparation of artificially digested food.

Dr. Henry Kennedy took exception to Dr. Purser's observations about the effect of pepsine, of which he had had favorable experience himself in children, with whom im-

agination could not be said to operate. How pepsine acted he was unable to explain. Some preparations of pepsine with glycerine were calculated to develop an unpleasant smell, which made it disagree.

Dr. Walter G. Smith regarded Dr. Purser's conclusions as founded on incontrovertible data. It was high time to protest against the illogical and irrational mode of using so-called aids to digestion.

Dr. J. W. Moore said that rectal alimentation was one of the principal uses of digestive agents, from the addition of which to nutritive enemata he had seen good results.

Dr. Atthill said he was sure Dr. Purser's remarks were based on scientific principles, but possibly some of his deductions were not strictly correct; because experiments carried on outside the body could not be identical with experiments inside. While sensible that there was a vast amount of humbug in the sale of digestive ferments, he did not agree with Dr. Purser that those ferments were absolutely useless, having himself prescribed pepsine with good results, especially in the case of children and delicate women. In artificial feeding per anum the peptonized food was of the greatest importunce.

Dr. Purser replied that he was prepared for the protest made as to the use of pepsine, and had anticipated the objection in his paper. As to the effect of medicine on children and delicate women, he did not say the effect was produced through the imagination; but he did not know anybody who gave pepsine and nothing else. The diet was always regulated to make it more easily digestible, and pepsine was prescribed with acid or aromatic water, and aromatic water would often cure gripes in children. To say the thing was different inside the body and outside the body showed an erroneous conception of digestion, which did not take place inside but outside the body. The mucous membrane of the stomach was just as much outside the body as the palm of the hand. The preparations for rectal alimentation were of some value.

An Eruption following Chicken-pox and Measles.

Before the New York Clinical Society, Dr. F. P. Foster presented a photograph of a child suffering from a form of skin disease, and read portions of two letters from Dr. T. L. Axtelle, of Waterbury, Connecticut, who had sent him the photograph.

"Briefly," wrote Dr. Axtelle, "the history of the case is as follows: Last May the child had varicella. Just as it was recovering from this, measles appeared. About the 1st of July, after convalescence from measles, the child was brought to me with a universal papulo-vesicular eruption, most abundant on the trunk, head, and face. This I pronounced acute vesicular eczema. A peculiarity was that the vesicles frequently became confluent, with a strong tendency to umbilication, with subsequent scabbing. This scabbing was chiefly on the face and head. I sent child and mother to the country in July. About the middle of August they returned, when the head was almost covered with one vast scab, with suppuration beneath. About a week before their return the eruption on the legs had appeared as papules, then vesicles, several coalescing and rising about one-eighth to one-fourth inch above the level of the skin. The summit was of a grayish color, and rather a rough, warty appearance. They contained no pus, and did not slough, scab, or scale. They gradually subsided to the skin level under salicylic acid ointment. The only scaly appearance was after they had returned to the skin level, when red scaly patches were left instead of the former nodules.

"I am at a loss to know what to call this. It was absolutely limited to the legs below the knees. Whether the first eruption was eczema, and this a form of the same, or whether I was wrong in the former diagnosis of eczema and the entire eruption is something else, I am uncertain.

"Two points I wish particularly to mention—namely, the eruption on the head and face and that on the legs existed in different stages of progress at the same time, but possessed no features of resemblance. That upon the head and face crusted and scabbed, while that on the limbs at no time manifested any such tendency. Nothing now remains of the nodules on the limbs except red patches marking the situation and size of the elevations."

Instances of Two or More Cases of Diabetes Mellitus in Members of the Same Family or in Near Relatives.

The late Dr. Austin Flint thus wrote in the *Jour. Am. Med. Ass.*, April 17:

Number of instances in which complete family histories were obtained, 36.

Number of instances in which but one case in a family was noted, 27.

Number of instances of two or more cases, 10.

No. 1. Father-daughter. (Both cases observed and recorded.)

No. 2. Brother-sister. (Case of sister only observed and recorded,)

No. 3. Mother-son. (Both cases observed and recorded.)

No. 4. Paternal uncle-nephew. (Case of nephew only observed and recorded.)

No. 5. Brother-sister. (Both cases observed and recorded.)

No. 6. Two sisters. (One case only observed and recorded.)

No. 7. Two sisters. (One case only observed and recorded.)

No. 8. Two brothers. (One case only observed and recorded.)

No. 9. Two brothers. (One case only observed and recorded.)

No. 10. Father, paternal uncle, two sisters, two brothers. (One case only observed and recorded.)

NOTE.—Nos. 1, 3, and 5 are reckoned each as one instance in the thirty-six.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

——The second number of the "Practical Notes on the Treatment of Skin Diseases," by Dr. George H. Rohé, of Baltimore, is devoted to eczema. It is a neat and instructive pamphlet of 46 pp. (published by Thomas & Evans, Baltimore).

——A study of fractures of the coracoid process appears from the pen of Dr. J. W. Byers, of Charlotte, N. C. It is a valuable contribution to the scanty literature of this rare accident.

——The use of cocaine in hay fever is advocated by Dr. Seth S. Bishop, of Chicago, in a tract before us. He employs a six per cent. powder of cocaine and sugar of milk in an insufflator.

——The influence which may be exerted on the central nervous system by hypertrophied labia minora, is set forth in a short paper by Dr. C. L. Gwyn, of Galveston, Texas. He traces to this condition many cases of general nervous irritation, nymphomania, etc.

——Those who would acquaint themselves with the remarkable researches of Dr. Domingos Freire on vaccination as protective against yellow fever, should obtain his pamphlet published in the French language, entitled *Le Vaccin de la Fièivre Jaune*, which may be ordered directly from his home, Rio Janeiro. This pamphlet gives a summary of the results of his practice between January and August, 1885.

——Several curious instances of supernumerary mammary glands and nipples are described in a reprint by Dr. William A. Edwards, of Philadelphia.

——A blank Note Book for cases of Ovarian and other Abdominal Tumors, adapted from the note books of Dr. Spencer Wells and the Samaritan Hospital, London, has been prepared by Dr. John Homans, of Harvard College, and published by Cupples, Upham & Co., Boston. It will be found quite convenient.

——Dr. William A. Byrd, of Quincy, Illinois, sends a reprint reporting a case of successful amputation of the hip-joint.

——A useful pamphlet of instruction to pathologists has been published at the State Hospital for the Insane, Norristown, Pa. It is entitled, A Brief Synopsis of the Various Points involved in the Coarse Examination of the Brain and Spinal Cord," by Francis K. Dercum, M. D. (8vo., pp. 11.)

BOOK NOTICES.

A Reference Hand-book of the Medical Sciences. Edited by Albert H. Buck, M. D., Vol. II. New York. William Wood & Co., 1886.

This very handsome and excellently edited work cannot be spoken of in other words than with praise. It comprises over 800 large, double column, quarto pages, on first-class paper, and in clear, though rather small, type, with numerous wood-cut illustrations scattered liberally through the text, and a series of full-page chromo lithographs, exhibiting in their natural colors various surgical and botanical subjects.

As our readers were made aware from our previous notice, the work is in fact a dictionary of medicine of the most complete kind. The present volume carries the topics down from "catarrh, nasal" to "eye," inclusive. Each entry of importance is written by some special contributor, who signs his articles, and thus gives the statements a personal guarantee which adds largely to the value of the whole. These contributors are nearly all residents of the United States, and include the most prominent medical writers of our country. With such judicious liberality on the part of the publisher, and with such a corps of contributors, one cannot doubt that the effect of this extensive undertaking will be highly improving to sound medical learning.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

NERVOUS DISEASES AFTER RAILROAD ACCIDENTS.

When a serious accident happens on railroads, the more visible lesions are generally the only ones reported. But after injuries to the head, and after all accidents which are accompanied by more or less concussion, by more or less shock, the immediate consequences are often the least dangerous, and the injuries which the nervous system receives, and which generally make their appearance later, are more important than the morbid signs first visible at the time of the accident.

That the subject has received special attention only of late cannot surprise, for the attending surgeon, after the wounds have healed for the treatment of which he was called in, leaves the patient apparently restored, and often never hears of him again. But of late the grave consequences of such accidents to the nervous system have become more frequent, probably because the concussion suffered by the victims of modern railroad wrecks is severer on account of the greater swiftness of the trains.

Charcot considered the nervous phenomena which so often develop after the immediate consequences of these injuries have disappeared, to be of an hysterical character; and this view has been held by most observers until Dr. H. Oppenheim, Assistant to the Nervous Clinic of the Charité Hospital in Berlin investigated the subject and published the result of his researches in the *Arch. f. Physiol.*, Bd. xvi., H. 3, '85.

From this report we learn, that the psychical disturbances occurring after such accidents usually assume the character of hypochondriasis, while amongst true neuroses hysteria, epilepsy, and various forms of neurasthenia are observed. That we have to do in these cases with genuine neuroses is apparent from a group of symptoms very common in these cases: stubborn headache, vertigo, vomiting, disturbances of motion, impairment of motion, impotency, difficulty in micturition, sensation of a tight band around the trunk, and even immobility of the pupils and atrophy of the cystic nerve.

But though these nervous phenomena in all these cases have more or less the same fundamental character, they are grouped differently in different cases. In some the picture they present does not fit into the frame of any one group, and many cases show a mixture of psychical and nervous symptoms, and are, therefore, partly psychoses, partly neuroses. In many instances we, besides, observe signs which clearly indicate a chronic grave lesion of the central nervous system.

Dr. Oppenheim lays special stress on the importance of not considering simulation, when the group of symptoms is such as not to harmonize with our view of what it should be. So many psychical and nervous anomalies are often observed in these cases, that we should long hesitate ere we ascribe to simulation what after all may be a grave lesion.

Concerning prognosis, O. has never yet seen a case of complete cure. Especially when the symptoms occur in an employee, who continues in the service of the company, the prospects of a cure are very small. In some cases the symptoms are in the beginning for a long time mild, and then assume a graver aspect, a point well to be remembered in the prognosis.

THE EFFECTS OF INSUFFICIENT FOOD AND OF STARVATION.

We often find, especially amongst clinical patients, all kinds of organic lesions without being able to determine the pathogenic element, for these morbid alterations are met with in individuals who have never been in the habit of using alcoholic stimulants, and who neither suffer from malaria, syphilis, nor any other dyscrasia. It is probable that the recent experiments of Drs. Posashni and Ochotin, of St. Petersburg, Russia, may throw some light upon these cases. The former made over fifty experiments in the laboratory of Prof. Pashutin on three dogs, of twenty-two hours' average duration. He investigated the respiratory gases of starving animals. The exhaled watery vapors, CO_2, and the inspired oxygen were quantitatively determined. The results of these researches were as follows:

1. The temperature of starving dogs diminishes only one or two days before death.

2. The percentage of loss of weight is most considerable at the beginning of starvation and immediately before death.

3. The quantity of urine greatly diminishes the first few days, but increases in proportion to the weight of the body as death draws near.

4. The absolute quantity of exhaled watery vapor diminishes from one-half to one-third the first few days, and then continues at that height until life is extinguished, while the quantity of carbonic acid exhaled diminishes in the same ratio as starvation increases.

5. The animals use at the beginning of starvation less oxygen than later, near death.

Dr. Ochotin limited his experiments to the pathological anatomical changes of the organs of rabbits partly starved, *i. e.*, such as did not receive a sufficient quantity of food, or food nourishing enough fully to sustain life. It was found that animals which for a long period received only about one-fourth of their accustomed food showed the same morbid changes as those which for a day or two were well fed, then for a number of days received no food, then again had plenty given them, etc.

All the animals thus insufficiently fed sooner or later showed atrophy of the organs, granular and fatty degeneration, proliferation of interstitial tissue, and division of cellular nuclei (rariokinesis). The changes were less only quantitatively than those caused by complete starvation.

KERNIG'S FLEXION-CONTRACTURE.

Not long since we reported the observation, first made by Kernig, that in some brain-diseases, as soon as the thigh is flexed the knee and also the elbow-joint become flexed, not allowing extension. Dr. W. Bull, of Christiania, has observed this phenomenon three times, and publishes his notes of the cases in the *Berl. Klin. Woch.*, 42, '86. One was a case of tubercular meningitis, the second one of tumor of the cerebellum, and the third one of thrombosis of the transverse sinus. The last two cases occurred in boys respectively 11 and 16 years old, and a post-mortem examination was permitted only in them.

The symptom mentioned does not appear to be pathognomonic of any special brain disease, but seems to occur in various lesions of the brain. Should further observations, however, demonstrate the fact that this sign sets in very early in tubercular meningitis, it would be of great clinical importance.

The explanation of the phenomenon is the following: Healthy individuals can extend their knees perfectly only, if the angle formed by abdomen and thigh is not less than 90°. As soon as the thigh is flexed more, so that it forms with the abdomen a more or less acute angle, the knee-joint cannot be straightened out to an angle of 180°. The bend of the knee then remains in an obtuse angle, and further extension is prevented by contraction of the posterior muscles of the thigh. As a consequence of this fact, the test should be made only with the thigh at right angles to the abdomen.

In healthy persons the mild contraction of the posterior thigh muscles which ensues on extending the knee-joint while the hip-joint remains in rectangular flexion does not cause any reflex effect. But in an individual suf-

fering from a lesion of the brain, especially compression, this mild contraction suffices to serve as an irritant, which in its turn produces a spasmodic contracture of reflex character in the respective muscles, which yields only when the irritation ceases on extending the hip-joint, and thus relaxing the posterior muscles of the thigh.

THE NEW DISINFECTANT, IODOL.

Silber and Crammician, in Rome, recently discovered a new disinfectant, "iodol." In etherial tar oil amongst others pyrrol is found, which when treated with biniodide of potash produces a crystalline union, tetraiodi depyrrol, C_4I_4NH—iodol. It is a light brown powder, which if not pure gets darker under the influence of sunlight. Its faint odor resembles that of thymol. In water it is scarcely at all soluble; easily in alcohol. A twenty per cent. alcoholic solution of iodol may be mixed with an equal quantity of pure (free from water) glycerin, without becoming opaque. All solutions of iodol, if at all concentrated, have a brown tint, also fats and cosmoline, to which iodol has been added. It is employed as a dressing for wounds, either in the form of fine powder or with cosmoline, or dissolved in alcohol (2–3 : 35 alcohol) diluted with glycerin to 100. It causes no intoxication by absorption from wound.

Notes and Comments.

Paralysis Following the Injection of Iodo-glycerine for the Treatment of Spina Bifida.

To a recent meeting of an English medical society, Dr. Lycett exhibited a girl, aged 6, who, at birth, was the subject of spina bifida over the upper part of the sacrum, forming a tense sessile tumor, of the size of an orange, having an ulcerated surface of the area of a crown-piece, which, on healing, formed a thin membranous covering to that portion of the sac. As it became thinner through expansion, it was tapped when she was six weeks old. An ounce and a half of fluid was drawn off, and forty minims of iodo-glycerine injected with a negative result. The sac refilled about a week afterwards; about an ounce of fluid was withdrawn, and the injection increased to a drachm and a half, causing the sac, in a few days, to become obliterated. Co-incidentally with the shrinking, however, came loss of sensory and motor power in the legs, with incontinence of fæces and urine; the paraplegia, which persisted, being complete below, and incomplete above the knees. Hydrocephalus also commenced immediately after the operation, and gradually increased until the third year, when the fontanelles closed without developing any nerve-phenomena, or impairing the mental power. The horizontal circumference of the head now measured 22 inches. In the report of the committee appointed by the Clinical Society of London to inquire into the subject of spina bifida, there was a case recorded, where paralysis supervened and persisted after the cure of the tumor, and appeared to be due to the treatment adopted. In several cases, temporary paralysis occurred, which passed off in a variable time; once complete paraplegia, which subsequently disappeared. In three cases, hydrocephalus set in subsequently to the cure of the spina bifida. Of the various operative measures, that by the injection of iodo-glycerine was recommended in preference to any, as promising the greatest success, though the table of results showed that of 71 cases, only 35 recovered, 27 died, 4 were relieved, and 5 unrelieved. As evidence of the frequency and serious nature of this affection, it appeared that it caused no fewer than 647 deaths in 1882, of which 615 were in children under one year of age.

Method of Treating Fractured Clavicle.

At the meeting of the Manchester Medical Society, on February 17, Mr. C. E. Richmond demonstrated an easy method of treating this injury. The position adopted was similar to the French one; the palm of the hand of the injured side being laid flat on the chest. The best position for adapting the ends of the fragments was first ascertained by abducting the elbow from or approximating it to the sternum. A piece of broad strapping was passed round both arm and body, to fix it in the required position. A piece of calico, twelve inches broad (more in a big adult), and in length sufficient to go twice round the body, was torn longitudinally, so as to make a four-tailed bandage, leaving about the middle eighteen inches untorn. This centre part was then grooved round the elbow, and the two lengths of the band (a), that lay next the body, were taken one up in front of the chest, over the flat hand, and the other up behind. These were then knotted together behind the sound shoulder, the ends being meanwhile held out of the way. The other two lengths (b) were taken round the arm and body in front and

behind, and also knotted behind and below the sound shoulder. The (a) ends were then brought down, one in front and one behind, and knotted betwixt the fixed elbow and the body, and then cut off short. The (b) ends were then again brought round the body over everything, and finally knotted in the hollow above the fixed elbow. Wadding was then inserted under the knots to prevent them from galling, and the hand against the chest was secured to the length of bandage, passing over it by means of a strip of calico passed round both. The advantages claimed were these: 1. There was no necessity for special apparatus. 2. The arm was fixed in the most favorable position. 3. The fixing was permanent. The method had been used in numerous cases with the best results.

Croupous Pneumonia and Gangrene of the Lung; Death; Necropsy.

The patient, a boy six years of age, lost both parents from lung disease, a sister had a leg amputated for disease of the knee, while another sister suffers from keratitis and caseous cervical glands. The patient has always been delicate, and for some months he has had a cough. When admitted into hospital he was found by Dr. Oxley (who reports the case in the *Lancet*) to have a very rickety chest, his temperature was 103°, and his respiration 44 per minute. His cough was frequent, and he had a scanty, viscid, yellow expectoration; the breath was rather foul; he had also signs of consolidation of the lower lobe of the right lung. In two days the breath became extremely offensive, the odor being fæcal in character and permeating the whole ward; signs of a cavity also appeared in the base of the right lung. The consolidation gradually crept over the whole lung, the pulse becoming more and more feeble. The smell persisted, though not quite so offensive as at first, owing to antiseptic inhalations. The patient died after being in hospital thirteen days.

After death the right pleura was found generally adherent; the right lung was in a state of gray hepatization; the lowest lobe contained a cavity about the size of a small orange; the walls were rough and of a dark greenish-blue color, it contained some ichorous fluid; there was a second smaller cavity in the middle lobe. The lung substance round these cavities was of a pale greenish-blue color; the tissue in the upper lobe was of a pale fawn color, and was absolutely airless. The left lung was œdematous. The mediastinal and bronchial glands were caseous, and in most of them the caseous material was more or less calcified. None of the glands were gangrenous. There was no heart disease. No tubercle was found in any part of the body.

Antipyrin in Pernicious Forms of Malarial Fevers.

Dr. John Hope Potter writes to the *Lancet* that while in charge of the Police Hospital of Bombay during his tenure of office as Acting Police Surgeon, he had considerable opportunities of testing the effects of different kinds of treatment in malarial fevers, of a remitting as well as an intermitting type. In common with most men who have had much experience of these fevers, he met many cases of a remittent type which were not amenable to the ordinary treatment, whether by quinine, arsenic, or diaphoretics with aconite. He determined to try the effect in such cases of administering antipyrin in sufficiently large and repeated doses to ensure a reduction of the temperature to the normal standard. The result was most satisfactory, so much so that during the last five months of his tenure of office he found no case that was not amenable to this treatment. Many cases that for weeks had been quite unaffected by the ordinary remedies were instantly cured by the exhibition of antipyrin followed by quinine. The few cases in which he found the effects unsatisfactory eventually showed other complications, such as abscess of the liver or phthisis. He is of opinion that in pernicious forms of uncomplicated remittent fever we have a most valuable aid to treatment in antipyrin.

As he is not aware that this treatment has been advocated in the malarial fevers of the tropics, he writes to give the result of his experience, in the hope that it may prove of use to those who have to contend with this common and only too fatal disease.

Permanganate of Potassa—Amenorrhœa.

Dr. Lee O. Rodgers, of San Francisco, reports the following case to the *Med. Record:*

"Miss F., aged nineteen, was sent to me for advice, and gave the following history: She leads an active life when at home, spending much time in the open air. In July, 1884, she came to a town adjacent to this city on a visit to friends. She began shortly after to grow 'stout,' her abdomen particularly becoming prominent. Her menses disappeared entirely after the period in July, previous to which she had always been per-

fectly regular. In March, 1885, she was sent to me by her hostess, who thought her pregnant, for the purpose of being kept in the city and confined. The girl seemed to be remarkably healthy, and was very 'fat,' and she proved, upon physical examination, to be a virgin. I immediately put her upon potassium permanganate, a two-grain compressed tablet four times a day, each tablet to be followed immediately by a large gobletful of water. Much nausea and some vomiting occurred during the administration of the medicine, but I attributed this to the fact that I gave the tablets on an empty stomach, as I accepted Bartholow's theory of the action of the drug. On the fourth day of the administration of the permanganate the menses appeared and lasted four days, after which the patient was sent to her home. She was instructed to inform me if her menses failed to appear on time after her return home, but I have not heard from her yet."

Hysteria in Soldiers.

Dr. A. T. Ozeretskovski describes in the Russian *Medical Review* a whole series of cases of hysteria occurring in soldiers, presenting nearly all the phenomena usually associated with this affection as it occurs in females—dumbness, deafness, deaf-mutism, various disturbances of vision and of general condition, spasms and paralyses, troubles connected with micturition, joint trouble, elevations of temperature, &c. The subsequent history of the cases in most instances left no doubt of the correctness of the diagnosis. Predisposition and heredity played a large part in the etiology, in and some instances there was injury or shock. Half the patients were recruits, which tends to show that the sudden change from domestic life and work to the arduous conditions of military service is not without effect on the nervous condition of the Russian soldier. The treatment of the hystero-epileptic cases was always unsuccessful, neither water, electricity, nor narcotics appearing to exert any influence over the frequency or severity of the attacks. The cure of the paralytic forms of the disease was successfully accomplished by means of exercise, gymnastics, &c.

Hepatic Origin of Urea.

Dr. D. W. Aitken describes, in the *British Medical Journal* of February 6, 1886, the following interesting case, the direct bearing of which upon the question of the source of urea is evident:

Early this month (January) I was called to see a boy who had the day previous received a rather severe blow upon the right lobe of the liver. When seen he was complaining of much pain in the right hypochondrium. The skin was slightly, and the conjunctiva distinctly jaundiced. The stools were pale, while the urine was bile-colored, and gave the bile reaction with nitric acid; there was no fever. But herein lies the important matter. The urine was highly alkaline. On the addition of nitric acid there was such violent effervesence that the froth was forced out of the test-tube, although the urine was not much more than one inch deep. I got my friend, Dr. Drinkwater, to examine the urine carefuly. He reports that the alkalinity was due to ammonium carbonate, and, on estimating the urea, he found only three per cent.

This evidence seems to point strongly to the liver as the seat of production of urea. Dr. Graves has already reported several cases of absence of urea which he believed to be represented in the urine by the ammonium carbonate, but here we have a history of the organ involvved.

Nitro-Glycerine in Chronic Nephritis.

After discussing this form of treatment and relating several cases in the *Medical Record*, Dr. Francis Kinnicutt thus concludes:

"My investigations, so far as they have been carried, permit of the following summarization:

"1. That in nitro-glycerine, given in small doses and frequently repeated, we possess a powerful agent for lowering the increased blood-pressure which is very constantly associated with the development of uræmic symptoms.

"2. That it has the power to control or relieve many of the paroxysmal disturbances of the nervous system which are included under the general term of uræmia; of these headache and asthma are especially benefited by its use, the relief being more marked and continuous than that obtainable either by opium or chloral.

"3. That its influence upon the daily excretion of urine and serum-albumin in parenchymatous and interstitial nephritis is apparently to increase the former and diminish the latter.

"4. That in the systematic and prolonged use of nitro-glycerine, in appropriate doses, in chronic nephritis, we possess a means of maintaining more or less continuously a

lowered blood-pressure, of often averting or relieving critical conditions, and thereby prolonging life."

Fœtid Bronchitis.

Before the Academy of Medicine in Ireland Dr. H. Kennedy detailed two instances, both in young females, where a very profuse expectoration, attended by a most offensive odor, occurred. The fetor was so great as to diffuse itself through a large ward, like what occurs in gangrene of the lung. The physical signs were in each case confined to one lung, and were what is now known as chronic strumous pneumonia. In each case there were slight signs of hectic, with the nails curved; whilst menstruation was irregular. Under the use of a combination of powdered uva ursi and charcoal, the patients improved much in their general health, and the fetor quite ceased at the end of ten days, and in about a month each patient left the hospital to look for places as servants. No local treatment in the way of inhalation was used.

Dr. Hayes instanced the case of a woman in Dr. Steevens's Hospital whom he had seen at the request of a colleague; the patient was the subject of a fetid bronchitis. He suggested an inhalation consisting of a combination of creasote, carbolic acid, iodine, and spirit, and the fetor disappeared entirely in a few days.

Spinal Curvature.

Before the Midland Medical Society, Mr. William Thomas exhibited two patients suffering from Angular Curvature of the Spine, each of them wearing an inexpensive jacket which he desired to bring before the members of the Society as a useful method of treatment. The principal feature of the jacket was a support of soft Swedish iron, which could easily be adapted to the changing shape of the spine, and could readily be arranged to support the head. This was applied closely to the spine, and, being sewn into a jacket of jean, was kept in position by lacing up the front. He claimed for it greater facility of application, more ease to the patient, less cost, and better results, than from treatmeut by the plaster jacket.

Inhalations in Pulmonary Tuberculosis.

In the *Revue de Therap.*, Rienzi presents the following results of numerous observations upon the treatment of pulmonary tuberculosis by medicated vapors:

1. Inhalations of minute quantities of the vapor of iodine, and of a mixture of iodoform in turpentine, induce amelioration of the local condition and of nutrition, but do not modify the fever, diarrhœa, or night-sweats. The mixture last named consists of twenty-five parts of turpentine to one of iodoform. Two to six drops of this are to be hourly volatilized in an apartment of average size.

2. Inhalations of sulphuretted hydrogen (four cubic inches of the gas to each cubic yard in the room) and of sulphurous acid, augment the general and dynamometric strength of the patient, and have a beneficial effect upon nutrition and renal excretion. The sulphuretted hydrogen possesses an especial action upon the respiration, which, together with cough, is diminished in frequency.

Sponges in Ovariotomy.

Dr. Lombe Atthill tells us in the *Medical Press* (March 3) that he uses only a small number, and these he makes use of over and over again. He finds that ten small and three large flat ones are, as a rule, all that are needed. If you have a large number in use, they are apt to be mislaid. He has seen the abdomen searched all over at the end of an operation for a sponge which had rolled unnoticed into a corner of the room, where, if only a limited number had been used, one, if dropped, would have been missed at once. But he always has two in reserve to replace any which, from having dropped on the floor, or from any other cause, may be deemed unfit for further use. The operation being over, he washes the sponges himself in pure water thoroughly, and then leaves them soaking for twenty-four hours in a solution of the perchloride of mercury, of the strength of 1-1000; squeeze them out of this, and dry them thoroughly, and they again go through the same process before being used.

Acute Febrile Pemphigus.

Dr. Chas. E. Gooding reports a case of this rare disease in the Canada *Medical and Surgical Journal.* A negress of thirty-one, who had always been healthy, noticed several small slightly raised spots on her chest, attended by moderate itching. In the evening, there was headache, malaise and fever, which increased in intensity. Small vesicles appeared in the spots, and, in a few days became bullæ. The whole body became covered except the legs, palms and soles. The bullæ burst, crusts formed, and pus oozed from under them. She was seen at this time,

and emitted a horrible stench. Diarrhœa set in, the patient became progressively weaker, and finally died of exhaustion on the 24th day. Patches were noticed on the pharynx and uvula, and the author regarded them as a mucous involvement of the same disease. He also looked upon the diarrhœa as caused by a similar affection of the gastro-intestinal tract. This view is quite probable, on account of the intensity of the attack and its rapidly fatal effect.

Pichi.

Among the remedies of local repute in South America which the energy of Messrs. Parke, Davis & Co. is introducing to the profession at large, one of the most interesting is *pichi*. The specific name of this drug is *Fabiana imbricata*, and it belongs to the natural order *Solanaceae*. Its active principle appears to possess the power of markedly stimulating the hepatic, renal and stomachal functions, expending its force on the excretory organs. In Chili, where it grows abundantly, the shepherds employ it for the relief of hepatic hydatids in sheep, and calculous disorders in the human subject. It may be classed among the digestives and diuretics. From a sketch of its properties furnished by Dr. Henry H. Rusby in the *Therapeutic Gazette*, it seems to be worthy of careful attention. Those of our readers who would investigate this remedy further may obtain information by addressing Messrs. Parke, Davis & Co., of Detroit, Mich.

Carbolic Acid in Indigestion.

In a recent number of the *Practitioner and News*, a correspondent says:

"I have just passed through a severe attack of indigestion accompanied by colic, pyrosis, food eructations, epigastric weight, uneasiness, etc. Alkalies, muriatic acid, pepsine, and pancreatic extract, failed to give relief. Seeing your note in the *American Practitioner* on the use of carbolic acid in acid eructations, etc., I took, with almost instant relief, two or three drops of the acid as soon after food as regurgitation, distension, or acidity occurred. One dose was usually sufficient. On two occasions only was a second dose required. This I took half an hour after the first. I dropped the acid on a bit of fresh bread, and rolled the mass into a pill. Since my own case, I have given it in a similar case with like good result. Here I added a scruple of carbolic acid to one ounce of glycerine. Dose, a teaspoonful."

Malthus's Law and Tumor-Growth.

Dr. Jonathan Hutchinson writes as follows, to *The British Medical Journal* of March 20, 1886:

Malthus's law of population-increase by geometrical progression applies to the growth of tumors. The larger they have become, the more rapid is their rate of progress. It is a process of cell-multiplication; and the more numerous the cells, the greater the result of their doubling. It is important to remember this law, since it may help us: first, in prognosis; secondly, in emphasizing the importance of early treatment; and, thirdly, as showing the occasional advantage of methods of treatment which diminish bulk and retard growth, although there may be no hope of cure.

The Malthusian law is often remarkably illustrated in cases of rodent ulcer, which advance very slowly at first, and very rapidly later on.

Indirect Cerebral Syphilis.

Under this name Dr. F. Lavergne (*France Medicale*) desires to classify those cases in which the brain lesions are secondary and consecutive to those of the neighboring bony structures. He treats of the clinical history and necropsy of this affection in a thorough manner, and calls attention, and justly too, to the fact that the prophylactic means must be used early and energetically to prevent disastrous results. Later on, antisyphilitic treatment will not avail. The lesions have become vulgar, and require treatment such as indicated, and not of a specific nature. By careful examination and observation the cranial involvements of syphilis will oftentimes be recognized early enough to prevent the more dangerous complication of syphilitic brain implications; and an energetic course of mixed treatment will always do this, if given in time.

Nocturnal Incontinence of Urine.

In the *Journal de Med. de Paris*, Dr. Ziem confirms the statement made by Dr. Major, of Canada, that nocturnal incontinence of urine occurs very frequently in children who are forced to breathe through the mouth by reason of some nasal obstruction. He rests his assertion upon some cases recently observed by him, and he regards it as very probable that the infirmity might be cured by the re-establishment of the normal mode of respiration. The author endeavors to explain the relation existing between buccal respiration and nocturnal incontinence of

urine, by regarding the latter as due to insufficient hematosis and a consequent accumulation of carbonic acid in the blood.

Cholera.

Before a foreign medical society, Dr. William H. Pearse read a paper on cholera. He argued that the facts of miasmatic contagion, and of the autogenesis of cholera must both be admitted, and were embraced in a greater theory of evolution. He applied Darwin's hypothesis of autogenesis to the autogenesis of cholera; he maintained that changed environment had been followed by cholera; and held that vito-chemical poisons evolved, after periodic intervals, from varied "shocks," or extremes of environment. Dr. Pearse applied the doctrine of "continuity" to cholera, and suggested the method of co-ordination to those not visibly affected.

Cocaine in Vaginal Operations.

A foreign exchange tells us that Dr. Yakub has successfully employed a twenty per cent. solution of cocaine in two gynæcological operations, kolpo-perineorrhaphy, or, to give it a less alarming name, suture of the perineum and vagina, and the removal of a papilloma from the posterior wall of the vagina. The solution was applied five or six times, and complete local anæsthesia produced. Both the wounds healed by first intention.

Francisceine.

Francisceine, according to the *British and Colonial Druggist*, is proposed as the name of a new alkaloid which has just been extracted from the Brazilian manaca root,, the produce of the Franciscea uniflora and certain other species. The principle in question has a very powerful purgative and diuretic action, and is also possessed of diaphoretic and emmenagogue properties.

Sulphate of Thallin.

Dr. Britneff, having investigated the effect of sulphate of thallin in fifteen febrile cases —pneumonia, tuberculosis, and typhus—has come to a conclusion similar to that reported by Jaksch, Guttmann, and others, viz., that, though thallin is an active antipyretic, its effects are of short duration, the temperature generally rising soon afterwards with a rigor. He does not expect, therefore, that it will be found of much use in medicine.

Correspondence.

Sudden Blindness During Labor.

Eds. Med. and Surg. Reporter:

At midnight of March 20th, I was called to attend the accouchement of Mrs. H., primiparæ. Found matters progressing satisfactorily—vertex presentation—patient very nervous, and disposed to think that *no* one had ever surmounted the difficulties of the ordeal through which she was about to pass. Chief nurse (her mother) disposed to encourage this idea. At this visit I made careful inquiries concerning the state of bowels and bladder, which were answered to my satisfaction. Pains, however, seemed to be flagging and inefficient, and learning that sleep had been broken and insufficient for the previous 48 hours I administered a draught containing chloral hydrate, with the assurance that, after a few hours of repose, the labor would go on with increased activity, and went back to my office for a nap. On returning to the house after an interval of five or six hours, was told that she had had a nice sleep, and found the pains coming on with vigor and frequency. The head was now well down on the perineum, and each throe was accompanied with some of the lustiest shrieks it has ever been my lot to hear. Now comes the curious occurrence which is my excuse for this communication. *Suddenly*, and while the poor suffering one was exerting to the utmost her expulsive powers, and while I was encouraging her to hope that each effort might be the last (so near was the child to the threshold of existence), she became blind, *totally* and *instantly*. She inquired why her husband (who sat by her side on the bed) had left her, and also complained of the absence of her mother. Both assured her of their presence, which she then verified by touch, but exclaimed, "I cannot see." By this time it was broad daylight, the shutters wide open, but she did not appreciate the faintest *glimmer* of light. I examined her eyes, but there was no effect produced on the pupils by passing a strong light before them. They were moderately dilated.

To make a long story short, the labor was terminated in half an hour, placenta at once removed by Crede's method, the patient made comfortable, and I left the new-made father bragging about what a nice girl he had. For two days this lady remained in total darkness—could not distinguish a *glimmer* of light. On the third day a hazy luminousness was perceptible, the following one she

could tell where the windows were, and on the next her sight was *completely* restored. She had not suffered from any degree of dropsy at any time. The kidneys acted freely, there was nothing approaching to a spasm, no sparks or flashes of light before her eyes—in short, not a single bad symptom. The urine, as soon after delivery as was practicable, showed no albumen. What caused the the blindness?

Warsaw, N. Y.

Scarlatina in Utero.

Eds. Med. and Surg. Reporter:

Considering the rarity of the occurrence of scarlatina in utero, I think the history of the following case may be of interest to my professional brethren:

Mrs. A., aet. 32 years, of German descent, constitution and general health good, and having had scarlatina when younger, was delivered of a large male child February 15th, 1886, labor being normal and of short duration. During the two weeks preceding delivery she was in constant attendance upon her older child, three years of age, affected with the malignant type of scarlatina, and which died three days after her confinement. During the first week of the older child's illness she contracted a very sore throat characteristic of scarlatinal sequelæ with much hyperaemia and involvement of submaxillary glands.

Immediately after delivery, and upon examining the child, the characteristic rash of scarlatina was observed, which was well marked and general and clearly defined, and which ran a course of nine days; desquamation occurring from fifth day on, and as naturally and well marked in large and small flakes as in any older child. Temperature ran from 100° to 104°, which was highest on third day of life. Considerable nausea and diarrhœa were manifested on third and fourth days. No other symptoms excepting the characteristic rash, elevation of temperature, nausea, and diarrhœa, presented themselves. I present this case as one of some interest, and considering the circumstances surrounding the case, consult the opinions of the older members of the profession, and ask of them in behalf of their professional experience if it was not one of scarlatina in utero. The mother and child made a good recovery, with no untoward symptoms, considering the fact that she was confined in the same room where an older child sickened and died.

News and Miscellany.

Insanity Among New England Farmers.

The vital statistics of the State of Maine show that there is a larger percentage of insanity in the farming class than in any other, and the publication of this fact has excited general surprise. The popular presumption is, that farming life, through its freedom from daily excitement and mental stress, its out-door life that favors vigorous bodily exercise, keen appetite, and sound digestion, ought to contribute a smaller per cent. of insane persons than city life, that includes so many restless brain-workers of all sorts.

The truth is, as a Vermont writer has said, that the average farmer of New England in the small towns, and also the farmer's wife and daughters, are not seldom as grievously overworked and as much subject to personal anxiety and nervous stress as the active workers of city life. To take a New England farm and make it pay, means toil—incessant toil—early and late. Physically, the farmer, and especially the farmer's wife, is often severely overworked, to the extent of a broken-down nervous system. The food of the farmer is no better, not always as healthful, as the food of mechanical city workers; and the fatigue, exposure, anxiety, and overwork of the average farmer are more than are ordinarily encountered by the city worker of the same intelligence. Give a farmer time to stop from his toil, and he is not without plenty of means of diversion for his tired body and mind. He can fish, he can hunt, he can boat and sail, if he can find time; but few farmers do find time; and, if they drop under their load, it is because, all things considered, they carry a more galling burden of bodily toil and mental anxiety than they are accredited with by those philosophers in the city who view the farm and farm-life through a glass of champagne. If anybody doubts that farmers have to work hard to get ahead, let him look at the number of broken-down, dyspeptic farmers' wives, barely turned of forty, that you can see at State and county fairs. The farmer cannot hide his land or his stock—it is inevitably taxed; and it is a smart, industrious, sober, energetic farmer that can make his farm pay six per cent. in New England. Hundreds of sturdy farmers in Vermont make less than this of their farms; and too many of them are tortured to death by the effort to pay for a farm they have bought, with a mortgage attached. If it be true

that the farming class contributes largely to the insane, it is not because they are brooders over the little, mean, local woes of life; it is because, as a class, they work very hard, both men and women; because they have to carry more anxieties and troubles, with less time for relaxation, than the city worker of the same grade of intelligence.

Nature of the Flavoring Principles of Brandy.

M. Ordonneau has lately made some investigations concerning the cause of the peculiar odor of brandy made from wine. That of brandy prepared from other materials, such as maize, beet, and potatoes, is characterized by what is known to French experts as the "odeur de trois-six," which is not present in wine brandy. The odor has been traced by M. Ordonneau to the presence of isobutylic alcohol. In genuine cognac brandy the predominating flavor is due to the presence of normal butylic alcohol, which is present to the extent of 218.60 grams per hectolitre. The production of this alcohol appears to be due to the presence of *Saccharomyces ellipsoideus* in the grape-juice, since it can be developed from the ordinary refinery liquid by fermenting it with the sediment of wine. The isobutylic alcohol, on the other hand, appears to be a secondary product of the fermentation with beer yeast. It might therefore be possible in future to obtain brandy of good flavor by fermenting malt liquor with the *Saccharomyces ellipsoideus*. The other flavoring product to which brandy owes its peculiar bouquet appears to be a terpene boiling at 178° C,, the products of the oxidation of which characterize old brandy. The author gives an analysis of cognac brandy, from which it appears that amylic and normal propylic alcohol and acetic ether form the principal ingredients, besides ethylic alcohol, although propionic, butyric, caproic, and œnanthic ethers, pyridine, and probably collidine, are present in minute quantities.

Cremation in France.

Decorative artists and sculptors are preparing to adapt themselves to the crematory movement, which has now in its favor a vote of the Municipal Council adopting the plan of a mortuary furnace, and granting a site in Père la Chaise, where it will soon be in operation. The expense of cremation is not, it is settled, to exceed fifteen francs. The municipality will, at a future sitting, vote the construction of a sort of lay temple, where families will be allowed to keep urns or other funereal vessels containing the ashes of dead relatives. This will not necessarily do away with any religious ceremony short of that of consigning the dead to consecrated ground; but as M. Koechlin Schwartz says, there is no reason why urns may not be consecrated, or why Protestants, Catholics, Jews, and Free Thinkers may not subscribe to build a vast mausoleum, in which the ashes of thousands could be deposited in beautiful vessels without injury to the living. It is probable that, cremation being now legal in such an art-centre as Paris, new and beautiful forms of artistic decoration will grow out of it. The time required for the combustion of an adult at Père la Chaise will be two hours.

Women Physicians Abroad.

The *Journal de Geneve* lately announced that among the 361 students in the University of Berne there are twenty women pursuing the regular course for the degree of Doctor of Medicine. This university has just conferred the degree of Ph. D. upon Mlle. Lina Berger, of the Grand Duchy of Baden, who passed an exceedingly brilliant examination. Two other ladies, one an American and the other an Austrian, took the degree of M. D. at the same time. But even in places where we least expect it are the women slowly gaining in honor and power. The University of Helsingford in Finland, for example, has conferred the degree of M. D., after a very rigid examination, upon Mlle. Heykel. This is the first Finland woman so honored, and the occasion was duly noted. A grand ovation was given to the graduate by her fellow-students, who at the same time opened a subscription among the people of Helsingford for a fund to establish a scholarship in the University for young Finnish women who desire to become physicians or surgeons. The "Rosine Heykel" fund thus far is in a flourishing condition.

A Chemical Garden.

The *Canadian Journal* tells us that a chemical garden is made as follows: Place a quantity of sand in a wide-mouthed bottle (or better, a half-gallon fish-globe) to the depth of two or three inches; in this layer of sand, slightly imbed a few pieces of sulphate of copper, sulphate of aluminium, and sulphate of iron; pour over the whole a solution of silicate of soda (commercial water-glass) 1 part and water 3 parts, care being taken not

to disarrange the chemicals in pouring in the solution. Upon standing a week or so, a dense growth of the silicate of the various bases used will be seen in various colors. Now displace the solution of the silicate of soda with clear water, by conveying a small stream of water through a small rubber tube (such as a nursing bottle tubing) into the vessel, which will gradually displace the silicate of soda solution. Care must be taken not to disarrange or break down the growth, with the stream of water. When successful, this produces a very beautiful scene.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE THREE WEEKS ENDED APRIL 17, 1886.

Wyman, Walter, surgeon. To represent the Service at the meeting of the American Medical Association, at St. Louis, Mo., April 12, 1886.

Sawtelle, H. W., surgeon. Detailed as chairman of Board for physical examination of officers of the Revenue Marine Service, April 15, 1886.

Urquhart, F. M., passed assistant surgeon. Relieved from duty at Norfolk, Va., May 1, 1886; to assume charge of Cape Charles Quarantine, April 16, 1886.

Yemans, H. W., passed assistant surgeon. Detailed as recorder of Board for physical examination of officers of the Revenue Marine Service, April 15, 1886.

Heath, F. C., assistant surgeon. Appointed an assistant surgeon, April 16, 1886; assigned to duty at Chicago, Ills., April 16, 1886.

Suicides in Great Cities.

It appears from recent statistics on this subject that Paris occupies a very unenviable position. The ratio of suicide for every million inhabitants averages yearly 402, while in Naples it is only 34. The French capital is thus the saddest as well as gayest city in Europe. The ratio for other cities is as follows: Stockholm 354 (this high average is quite unaccountable in the northern city, where the pressure of life is not great); Copenhagen 302, Vienna 287, Brussels 271, Dresden 240, St. Petersburg 206, Florence 180, Berlin 170, New York 144, Genoa 135, London 87, and Rome 74. London thus occupies a very advantageous position in the list. With regard to New York, it is said that the majority of the suicides of that city are German.

Micro-organisms and Magnetism.

M. Dubois has sought to ascertain the influence of magnetism on the development of microbes. After placing two powerful magnets in a certain position, he arranged a set of capsules containing artificial cultivations in a circle between the magnets. After careful observation, he was able to prove that microbes, under these circumstances, developed from northeast to southwest. The micro-organisms developed in a capsule situated in the centre exactly between the two magnets, remained rounded in the direction of the axis of the resultant of the two forces, represented by two lines crossing each other in the direction of northeast to southwest, and southwest to northeast.

Association of American Medical Editors.

The annual meeting of the Association of American Medical Editors will be held in St. Louis, May 3, 1886. The programme for the occasion has not yet been announced, but will embrace an address by the President, papers by well known authors, and perhaps a banquet.

Items.

—At Prof. Parvin's clinic was a woman who had borne *eighteen children* at full term. She was accompanied by her sister, who had borne *sixteen*.

—Elijah Lane is the tallest man in the State of New Hampshire. Mr. Lane is from Keene, and is 6 feet eight inches in height, and weighs 210 pounds.

—By the terms of Dr. Flint's will, his medical library is given to the Academy of Medicine, with the exception of such books as the family may wish to retain.

—Daniel Alspach, an aged and well-known undertaker of Orwigsburg, Pa., contracted blood-poisoning while laying out a corpse recently, which caused his death.

—One man advertised for a clerk and thirty-five responded to his call; another man advertised for five carpenters and he can't get one. This proves beyond a doubt that it does pay to learn a trade after all.

—The United States Consul General at Rome has telegraphed the Secretary of State that there were sixteen deaths from cholera at Brindisi from April 8th to the 16th inst.

—Dr. William Hunt denies that *Othello* smothered *Desdemona*, and insists that she died from "a fracture of the cricoid cartilage of the larynx." On the whole, it is perhaps

unfortunate that there wasn't a post-mortem in the case.

—There is evidently a decline in the consumption of alcoholic liquors in this country at the present time. It is shown by the decrease of the internal revenue receipts last year, amounting to $9,000,000.

—The Supreme Sanitatsrath of Vienna, having submitted nickel and nickel-plated cooking utensils to a careful chemical examination, has decided that their use, from a sanitary point of view, is not free from serious objection.

—The Archduke Charles Theodore of Bavaria, who practices medicine, has obtained permission from M. Pasteur to be present at the inoculations in the laboratory of Rue d'Ulm. The Archduchess, who helps her husband in his professional labors, will accompany him as an assistant.

—Acute inflammation and enlargement of the prostate is much relieved by the continued application of hot water to the perineum, and its injection into the rectum, giving directions for its retention. The pain often subsides in a very short time, and micturition becomes easier.

—The Academia Medica di Roma, on Sunday, March 28, Professor Guido Baccelli presiding, held an animated discussion on M. Pasteur's method in hydrophobia. Opinion as to its efficacy was much divided, and the discussion was adjourned till April 4.

—The meeting of the American medical editors for 1886 will occur in St. Louis, on Monday, May 3, the day preceding the meeting of the American Medical Association. The following are the present officers: Dr. H. O. Walker, President; Dr. F. L. Sim, Vice-President; and Dr. F. E. Daniel, Secretary.

—Dr. Schatz reports a case (*Centralb. für Gynak.*) of a young woman from whom he removed the whole of the left ovary for a cystic tumor; he also removed part of the right ovary, which had undergone cystic degeneration. The patient menstruated regularly, subsequently married, and in May, 1886, was delivered of a daughter at full term.

—Concerning a case of *diabetes* with gangrene of one finger, Prof. Bartholow said: Withdraw all starchy and saccharine food from diet; instead, use acid fruits and vegetables; if patient can stand it, skimmed milk is the best diet; certain mineral waters are useful, as the alkaline waters of Michigan and the Bethesda, of Wisconsin; large quantities are necessary, especially good in fat subjects; ammonium carbonate and sodium phosphate, the chloride of gold and sodium, and cod-liver oil, likewise serve a useful purpose.

—There are now enrolled, as members of the night medical service of Paris, 608 physicians and 356 midwives, serving from 10 p. m. to 7 a. m. During the year 1885, 7,494 calls were received from a population of 2,226,000 persons. Of these calls, 52 per cent. were to attend women, 32 per cent. to attend men, and 16 per cent. to attend children.

OBITUARY NOTICE.

Professor A. Bouchardat.

This veteran pharmacist and chemist died on April 7, at the age of eighty, at his residence in Paris. Appolinaire Bouchardat was born in 1806, at Isle-sur-Serein (Yonne), in Burgundy. He embraced the pharmaceutical profession, and came to Paris when quite a young man. He became *agrégé* in 1834, and was first pharmacist-in-chief to the St. Antoine Hospital, and then to the Hôtel-Dieu, where he remained from 1834 to 1855. At that time he resigned, to devote his time to scientific pursuits. In 1852 he obtained, by competition, the chair of physics and organic chemistry at the College of Pharmacy. He became, in 1850, a member of the Academy of Medicine, and was at his death a Commander of the Legion of Honor. His scientific works are very numerous, and some quite important. The subjects investigated were the following: the grape-vine, wine, milk, diabetes and glycosury digestion, hygiene, potable waters, chloroform, and many others. He published the "Annuaire de Thérapeutique, Matière Médicale, Pharmacie et Toxicologie," from 1841 to 1885, and the "Formulaire Magistral," which has had thus far twenty-five editions. Of late years he has had for these publications the collaboration of his eldest son, Jean, a surgeon-major of the first class. It was not Bouchardat who founded the *Répertoire de Pharmacie*, as is stated in a Paris pharmaceutical paper; it was Dr. Lartigue, who edited it from 1844 to 1847, when the deceased took the chair, which he occupied until 1872. Professor Bouchardat was almost unknown to the present generation of pharmaceutical students, but he was beloved by those of his time for his kindness and benevolence. His younger son, Gustave, is Professor of Hydrology and Mineralogy at the School of Pharmacy.

"Pallas Syringe." The most useful Instrument for Vaginal Medication and Irrigation.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

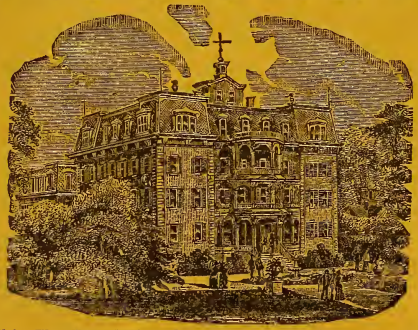
BURN-BRAE.



This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful Home.

Lecture.

SOME POINTS ON THE HEALING OF WOUNDS.

BY J. S. WIGHT, M. D.,

Professor of Operative and Clinical Surgery at the Long Island College (Brooklyn) Hospital.

(*Concluded from page* 546.)

In the next place, the drainage-tube deserves our consideration. While the drainage-tube, in one form or another, is useful to permit the escape of blood and serum, and thus diminish pressure and limit the quantity of waste material, it is by no means perfect in its work at all times. Much of the blood that oozes from the unclosed blood-vessels of small calibre not unfrequently coagulates outside of the drainage-tube, and so remains within the flaps to interfere with primary union. The drainage-tube is an admirable contrivance, not only for the removal of blood and serum, but also for the removal of the excess of proliferation. Antiseptic solutions can be run through properly-constructed drainage-tubes, so as to wash out the waste material and prevent the toxic effects of its absorption. The sure sign of such toxic effect is the elevation of the patient's temperature. And almost invariably, after the wound cavity has been washed out with an antiseptic solution, the temperature rapidly falls. For this there are two reasons: First, the waste material of proliferation and repair are washed out, so that it cannot be absorbed. Second. The proliferating cells are inhibited in their special activity, so that less waste material is formed. I have often noted a sudden rise of temperature, when waste material has been absorbed, whether from acute proliferation and suppuration, or from the accumulation of serous effusion and infiltration. And this event has frequently happened when there has been no infecting microbe present. It is then that the drainage-tube becomes a most valuable aid in the healing of wounds.

Who does not know that there is more or less swelling of the peri-jacent tissue in all cases of wounds? And if there has been an amputation, we speak of the change as a swelling of the flaps.

Let us look for a moment at the condition of things in these tissues. The severed end of every blood-vessel, large and small, will finally, on the arrest of hemorrhage, contain a blood-clot; and the peri-vascular spaces will contain more or less extravasated serum for a considerable distance beyond the wound surface. In one case this swelling will be moderate; in another, it will be considerable; and in still another it will be very great. And I have satisfied myself, after much observation and experience, that this coagulated blood, and this effused serum, have an important bearing on the question of healing of wounds. The more extensive this coagulation and the more marked this effusion, the more difficult will it be to obtain primary union. Indeed, all efforts to obtain primary union may be defeated by this condition of the blood-vessels. Even after the successful arrest of hemorrhage, when no blood-clots form between wound surfaces, and when everything at the outset promises speedy union, we may have excessive proliferation, profuse suppuration, followed by granulations and secondary union. And such results may be due to the extent of the

intravascular blood-clots and the quantity of the extravasated serum.

And if we search for the cause, we may find it in the severity of the injury that has devitalized the cells and paralyzed to a greater or less extent the nerves of the parts in which the wounded surfaces are located; or in the fact that the parts that have been wounded were already in a disordered condition, so that the blood-vessels could not properly retract and contract, and could not resist the copious extravasation of serum; or, in the blood itself, which has had its power to coagulate impaired, and whose serous portions have become prone to exosmosis; that is, extravasation; or, in the manipulation to which the tissues have been subjected during an operation, such as the compression and strangulation produced by the elastic bandage, and such as the prolonged and severe handling of the amputation flaps.

But if we search for a remedy we may not find it in every case—unless, perhaps, we leave all wounds open so that the blood of the primary oozing can escape, and so that the extravasated serum can run out. And even this does not meet the indications we seek. And to apply pressure to the flaps, for instance, I have seen to be frequently full of harm, for so resistless is the force of the extravasated serum that the already damaged tissues cannot support any competent pressure. But yet a certain moderate amount of pressure, for the purpose of diminishing the serous outflow, I have found advantageous, and would recommend. And in addition to this, if the wounded part can be elevated, that may contribute something toward the arrest of serous infiltration. But in regard to the arrest of oozing from the wounded surfaces, this desirable result may not always be attainable. In more than one case I have been deeply impressed with the following clinical history: For instance, a patient comes under my care with a crushed limb; the patient's life and the rest of his limb must be conserved; he is suffering from shock, and may die under a prolonged operation; after the administration of ether I amputate his limb as speedily as possible; then at once the large blood-vessels are ligated; the wound surfaces are rapidly washed with a warm antiseptic solution; an antiseptic dressing is put between the flaps, and an antiseptic dressing is put on the outside and firmly held in place by a bandage. The patient has had the least possible shock from the operation; he has free and copious oozing; he has abundant drainage; he has the minimum of swelling; he has a desirable amount of proliferation; he has the early formation of granulation tissue, which speedily grows the flaps together; and during all this there is little or no fever. And yet there are many cases in which I would recommend the most thorough arrest of hemorrhage, and a complete apposition of the soft parts after the following plan: Two or more sutures, inserted at some distance from the edge of the flaps and made to traverse them deeply, are tied so as to bring and hold the entire wounded surfaces face to face. This expedient will tend much to prevent oozing from the small vessels, and it will prevent tension on the sutures that are to co-apt the cutaneous edges, which should now be inserted at such a distance from the edge of the flap as not to interfere with the proper circulation, and so as to make the adjustment as complete as possible.

If the infliction of a mechanical, molecular, or chemical injury, of momentary duration, will cause such profound changes and such important results, then we may note the effects produced by infection and be able to comprehend them more readily, and accept the cause of the phenomena without incredulity. All wounds lead to proliferation in some degree; all proliferation brings waste material; all waste material is the pabulum of micro-organisms; hence, micro-organisms may invade any wound. Now, micro-organisms can multiply and persist in their work; they can produce a continuous irritation; and so they can keep up the process of proliferation; and so they can also keep up the work of suppuration. If these statements are correct, and I believe they are, there can be no question as to our line of duty. Are we not bound to use those remedies that experience has shown to be useful in preventing and arresting the development and growth of infecting micro-organisms? While we answer this question in the affirmative, we must not lose sight of the harm that may come from the practice of antiseptic surgery. For too much of a good thing may cause the gravest disorders. In great practical problems it is not always easy to fix the exact line of our work. I am not ready to condemn a piece of practice on the ground that I would do it in a different manner.

But there is one point of special interest to me in the practice of antiseptic surgery, and one that I have always looked upon as of primary importance, and upon its practical bearing I have always insisted: the cells of the wound-surfaces must always be kept in the best condition possible under the circumstances. Too often, it appears to be

thought only necessary to apply some kind of antiseptics in order, as is alleged, to keep out the microbes of sepsis. Just as if there were no harmful influences that could come from an injury or an operation. In some subjects it is indeed true, whether or not we can rightly explain it, that the proliferation incident to repair is excessive, and eventuates in profuse suppuration, which may go on for a longer or shorter time before healing takes place. And this form of suppuration may have no antecedent of septic infection, and no relation to septic intoxication. As already indicated, the judicious application of antiseptics to the tissues, that, under the action of some non-infecting irritant, are apt to take on excessive proliferation and suppuration, is most salutary practice. To inhibit and guide a recently proliferated cell, so that it can become a scar-tissue fibre, is one of the most praiseworthy acts of the practical surgeon. And because the antiseptic happens to be competent to perform this office, that is, it can inhibit the new cells as well as the microbes, we are not to conclude that the therapeutics of antiseptics begin and end entirely in the destruction of microbes. Hence we come to this conclusion: If there were no microbes, it would still be true that wounds would heal better under the careful employment of those substances called antiseptics, than they would to abandon them altogether.

Communications.

FRACTURE, WITH TREATMENT AND SUIT FOR MALAPRAXIS.

BY H. S. CUNNINGHAM, M. D.,
Of Indianapolis, Ind.

On the 12th of August, 1884, Mrs. B., while trimming grape-vines, fell from a step-ladder, and suffered a compound comminuted fracture of the tibia and fibula about one and one-fourth (1¼) inches above the ankle-joint. The soft parts were terribly lacerated and torn on the inner side of the limb, the laceration extending from the crest of the tibia to the tendo-Achillis, the lower fragment of the tibia protruding from the wound, and split in two antero-posteriorly, the foot being flexed upon the outer side of the leg. Both bones were broken at another point, about two inches above the fracture just described, but the soft parts were not visibly lacerated at this point. Mrs. B. was about forty-eight (48) years old, and weighed 250 pounds. She also showed a marked predominance of the lymphatic temperament. The previous history of the limb was not good, as she had suffered with œdema and varicose veins for a period extending over seventeen (17) years, and experienced much weakness when walking or standing upon it. The previous history of the limb, together with the nature and extent of the injury and a temperament indicative of a sluggish circulation and deficient action of the absorbents, led me to put it into the fracture-box; for by its use I could keep the limb in a more quiet and fixed position, and elevate the foot much higher than the body, forming an inclined plane, and not flex the limb at the knee, thereby favoring the returning circulation through the veins, some of which were already lacerated and destroyed, the long and short saphenous veins and their tributaries being more or less defective from broken-down valves. I bandaged the limb with white flannel, because of its elasticity, and placed it in a fracture-box, which was well padded and nicely moulded to the under side of the leg; the foot was secured to the foot-board, and extension kept up by the aid of adhesive plaster. Sand-bags were nicely moulded to each side of the limb, being careful to avoid undue pressure at any given point, to prevent motion. Oiled silk was placed under the wound, and then dressed with a carbolic lotion, drainage-tubes having first been placed in the proper position. Absorbent cotton and oakum were placed at the site of the wound, and the patient given an anodyne.

Mrs. B. was placed upon Hewson's fracture bed, as shown in Druitt's Surgery, page 255, the third day after the injury; or as soon as one could be constructed. Every effort was made to heal the wound, and convert the injury into a simple fracture as rapidly as possible. Close attention was given to the general temperature and circulation, and more especially to the local temperature and circulation of the foot and limb. About the fourth week dead bone was found at the seat of the fracture, on the inner side of the limb, by probing through a fistulous opening, but no detached spicula could be discovered. I then introduced a seton through this opening, which was situated near the crest of the *tibia*, and passed it down to the point where I discovered dead bone, and cut again just above the tendo Achillis. I hoped by this procedure to favor drainage, and possibly aid in the completion of union of the bones. About the fifth week the fracture-box was removed, when I discovered that the heel had an ulcer upon it, and the end of the os

calcis was slightly necrosed at the point of the heel, just below the insertion of the tendo Achillis. There were also two small ulcers upon the foot; one over the metatarsus, near where the metatarsal artery crosses the foot, the other over the cuboid bone, at the point where the tarsal artery crosses it. I have no doubt but what the anterior and posterior tibials and peroneal arteries were injured, and the tarsal and metatarsal arteries supplying the parts defective, resulting in sloughing at the points mentioned. I believe the sloughing and necrosis at the heel was due to the same cause, viz., defective nutrition from the internal calcarean, and a branch of the peroneal, supplying the tissues at the point of the heel. A day or two after the removal of the box, it became apparent that there was an accumulation of pus on the outer side of the limb, near the seat of the fractures. I made an incision, and after evacuating the pus I introduced the index finger into the opening, and explored for necrosed bone or detached spicula. I found portions of the shaft of the tibia denuded of periosteum, and roughened, or apparently *necrosed.* I solicited consultation with a skilled surgeon to assist me in cutting away the dead bone. I at the same time told Mr. B. that an amputation might be necessary if we found the shaft of the tibia almost entirely destroyed. A consultation was agreed upon, and Dr. W. B. Fletcher, present Superintendent of the State Insane Asylum, selected. We were to have met at six—6 p. m. of September the 23d, 1884—but between the hours of three and five p. m. Mr. B. called in two homœopathic physicians. They condemned me roundly for lack of knowledge and neglect, and advised Mr. B. not to pay me, but to sue me for damages for malapraxis.

Mr. B. then refused to pay me, and I brought suit for my fees. He filed a cross complaint for one thousand dollars damages for malapraxis, charging me with neglect, lack of skill and surgical knowledge, and of producing the sloughs through the improper use of iodine and undue pressure on the heel. The trial took place March, 1886, about nineteen (19) months after the injury. The patient, Mrs. B., was produced in court after three different affidavits had been filed at different times, testifying to her total inability to appear in court without greatly endangering her life—the last of which was filed about four hours before she was produced. She testified that her general health was good, but she still had a small open ulcer at the heel. In my defence of malapraxis, it was shown that there had not been undue pressure upon the heel at any time, and that the sloughing at the heel and necrosis of the os calcis were due to the same causes that favored sloughing on the top of the foot, viz., shock and injury to the vessels and nerves. The homœopathic attendant admitted his inability to account for his failure to heal the ulcer at the heel, and admitted they had never searched for dead bone, but believed there was none there, as no spicula had become detached and come away during their eighteen (18) months' surgical experience on Mrs. B. It was also shown on trial that there had not been over two ounces of tincture of iodine in the house during the period I was her physician; and that iodine would not produce gangrene or sloughing, but was frequently used to prevent such accidents. It was also shown that if there was gross neglect displayed in the attention given to Mrs. B., it was at the hands of the homœopathic attendants, who, after treating the patient for nearly eighteen (18) months, had failed to heal the ulcer at the heel, and yet had never searched for dead bone, to learn whether that prevented the ulcer from healing. It was also shown that the *sequestra* might be partially covered up in *cloacæ*, or undetached portions of dead bone might be covered up partially or entirely with new osseous or fibro-cartilaginous formation, and the soft parts heal for the time being, or even for years, and then give trouble or destroy the entire shaft of a bone and necessitate an amputation, all of which might have been avoided if the dead bone had been removed at the proper time. The jury were out fifteen (15) minutes, and returned a verdict for one hundred and twenty-five dollars ($125) for services rendered, and setting aside the cross-complaint for malapraxis and one thousand dollars ($1,000) damages.

ON THE NUTRITIVE VALUE OF SOME BEEF EXTRACTS: AN EXPERIMENTAL INQUIRY.*

BY THOMAS J. MAYS, M. D.,
Of Philadelphia.

During the last seven months my leisure time has been principally employed in efforts to determine the nutritive value of some of our principal beef preparations, and I beg your brief attention this evening for the purpose of bringing the results of these researches before you.

* Read before the College of Physicians of Philadelphia.

That there is no idea so erroneous as to be wholly devoid of truth, nor one so true as to be wholly devoid of error, is an ancient maxim, and its truth is probably as well illustrated in the prevailing ideas of the nutritive value of the beef extracts as it is in anything else. A study of the extensive literature of the beef extracts shows the inconstant and indefinite opinions which have been held concerning their action, and also illustrates the fluctuations of thought which the medical profession is liable to undergo. Liebig, who was one of the first to invest this question with scientific interest, held no less than three different theories regarding their action, during the last twenty years of his life. In his *Letters on Chemistry*, published in 1851, he distinctly rates the beef extracts as nutriments, *i. e.*, as substances which are capable of supplying working force to the muscles of the body. In *Auerbach's Volkskalender*, page 148, published in 1868, and in his *Chemische Briefe*, issued in 1865, he expresses the opinion that they are merely condiments (genussmittel), and, hence, only act as stimulants to the process of digestion, and to the general nutrition of the body. Later, he conceived the idea that they are nutrients not only in the sense of supplying force to the body, but as furnishing material wherewith the bodily tissues are constructed. Since his death, however, medical opinion has by almost universal consent reverted to the second idea entertained by him, viz., that the beef extracts are of no, or very little, value as foods. It is true that this has been questioned by some whose clinical observations have led them to different conclusions, yet I do not know of a single work on physiology, therapeutics, or pharmacology, that does not assign the beef extracts among the non-nutritious alimentary agents. Probably the most positive expression of this feeling among those who are considered modern authority on such subjects is that of Dr. Fothergill in his *Hand-book of Treatment*, or *Principles of Therapeutics*, who, on page 537, says that, "as a food, beef-tea ranks low. It contains meat-salts, a small quantity of albumen, and a little gelatine, together with some advanced nitrogenized matters useless in histogenesis. But there is little in it to repair tissues, and less in it to sustain life, so far as our knowledge yet extends. There is little real force-bearing material in the protean compounds of beef-tea. For the starving fever patient, to give him beef-tea alone is almost to give him a stone when he asks for bread. It makes him feel better for the time being, but that is due to its stimulant properties."

There can be no doubt that the cause of the prevailing skepticism concerning the nutritive value of beef extracts is largely due to the experiments which were made by feeding animals exclusively on the preparations, with the result that all of them died within a short period of time. Indeed, Kemmerich affirms that they died more quickly than those which were left to die from hunger. This has the semblance of proof that beef extracts are not capable of supporting life. Sober reflection teaches, however, that no animal can subsist continuously on any single food, and that such a test would unceremoniously refute the food value of any substance, no matter how nutritive it might be. But, beset with difficulties as this investigation evidently is, the question is not whether these substances are capable of sustaining life alone, but whether it can be shown that they contain nutritive value at all, and if so how much. Here everything depends on the method which is employed to determine this question. It is imperative that this should be definite and exact. It must be able to show the functional state and condition of the organism, before, during, and after the addition of these substances; or, in other words, it must demonstrate whether the organism is or is not capable of performing work when these substances are added to it.

To meet all these desiderata, I selected the isolated frog's heart, which has already proved itself so pregnant with good results in the hands of Ludwig, Cyon, Kronecker, Bowditch, and others, in the full belief that it will show itself as capable here as it has in clearing up other problems in experimental physiology. Only quite recently, Prof. Yeo (*Journal of Physiology*, vol. 6, No. 3, p. 93), has succeeded in demonstrating with it the reduction of oxyhæmoglobin, a phenomenon the existence of which was assumed, but never proven by direct observation.

The experiences of Prof. Kronecker, Drs. Martius, McGuire, Von Ott, and others, show very clearly that when the frog's heart is well washed out with a 0.6 per cent. saline solution and then allowed to beat with the same, its pulsations gradually get less in force and in elevation, until at last in the course of an hour or two it becomes entirely exhausted and is unable to work any longer. But when this stage of complete fatigue is reached, and the heart is filled with blood or serum, it recommences to beat, and its pulsations gradually gather in strength and in elevation until their former altitude is attained. If, instead of with blood, the heart were refilled with the saline, or any alkaline,

acid, or even alkaloid solution, it would never show any sign of returning vitality. This observation means that the saline, alkaline, acid, and alkaloid solutions are devoid of material with which the heart can perform its function, and, although it works while it is filled with these solutions, it does so at the expense of nutritive material stored up in its own meshes, and not with any energy derived from these solutions. Indeed, Dr. Pohl-Pincus (see *Verhandlungen der Berliner Physiologischen Gesellschaft*, Feb. 23, 1883) has brought forward evidence which indicates that in the wall of the frog's heart there exist lacunæ (Nahrspalten) designed for the purpose of storing up nutritive material. As soon as this stored-up supply is exhausted, it ceases to beat, and any solution which is now applied to it with a view to reestablish its pulsations must contain some elements which are capable of nourishing it. These essentials are found in the blood and serum of most animals. Dr. Von Ott (*Archiv für Physiologie*, March, 1883) has also shown that milk has the power of nourishing the heart. And Prof. Ringer (*Journal of Physiology*, vol. vi., No. 6), in following the same line of inquiry, found that both albumen and gelatine are capable of sustaining the heart's contraction. In my own work on the nutritive value of different concentrations of blood, performed in the Berlin Physiological Laboratory under the direction of Prof. Kronecker (*pub. Verhandlungen der Berliner Physiologischen Gesellschaft*, Jan., 1883), I found that the amount of work of the frog's heart performed with blood depends entirely on the degree of dilution of the latter agent. Dr. McGuire found, however, that 1 : 3—*i. e.*, one part of blood to three parts of saline solution—gave the best results.

In summing up the literature upon the action of the frog's heart in its relation to our subject, we find the following: That the heart in performing work consumes oxygen; that after it is once completely exhausted, it cannot resume its pulsations unless food energy is supplied to it from the outside; that blood, serum, milk, albumen, and gelatine are capable of acting as foods and of restoring its power of contraction, but no other substances have, heretofore, been shown to possess this property; that the pulse-elevations and the amount of work which the heart is able to do, depend in a great measure on the degree of concentration of the food. These data, moreover, demonstrate very fully that the heart does not exercise the function of a purely circulatory organ in these experiments, but that it is an organic medium possessed of the power of assimilation, of transformation of energy, of contraction, and of respiration.

(*To be continued.*)

HERNIOTOMY.

BY C. D. CHALFANT, A. M., M. D.,

Of Streator, Illinois.

In a recent issue of the MEDICAL AND SURGICAL REPORTER, some extracts from the paper read by Dr. Hyde before the New York State Medical Society, and remarks following by Dr. Gouley, bring to mind some reminiscences of practice which most fully verify the conclusions therefrom deduced.

It has been my fortune to meet with more cases of strangulated hernia than usual in the rounds of a general practice, and among this number it is my desire to report two cases in brief, one occurring several years ago, and the latter during the month of November last.

Case 1. Mrs. L., aged 55, was taken with slight pain in stomach; no pain in lower bowel; had similar attacks before, ascribed to indigestion. Careful inquiry as to having rupture or pain in inguinal region, elicited a negative reply. No evidence whatever pointing to hernia other than occasional pain in stomach. By chance, previous to leaving the patient, having some doubt as to diagnosis, my hand came in contact with a small tumor in right groin, size of filbert, and on inquiry found this little glandular enlargement had been present for thirty years. Although it had none of the characteristics of a hernia, yet I expressed a fear that such might be the fact. The husband, an educated gentleman, expressed surprise at my extremely pessimistic views of the case, and I asked for a council of at least two physicians, which was granted. Dr. McMan, of Gardner, and Dr. Bannister, of Odell, Illinois, were called, both gentlemen of good surgical ability, and with whom I had operated for hernia several times.

An exploratory puncture was made with negative results, and the severity of the symptoms not increasing, my colleagues were very positive I was in error, and a favorable prognosis was given.

Two days later patient was seized with stercoraceous vomiting, collapse, and death. Post-mortem developed small tumor immediately over inguinal canal, probably an enlarged gland, small piece of omentum, and

the smallest convolution of intestine possible, strangulated with it just beneath tumor.

Case No. 2. Mr. B., aged 40, had suffered for years with immense protrusion through inguinal canal into scrotum, and no appliance whatever would afford relief. On the literature of trusses and all the methods of cure he was an authority. He gave up his business to attempt a cure by the Heaton method, and moved to the city to be in proximity to the medical gentleman who was to undertake the case. Six months' injections of iodine and fl. ext. quercus alba had served to benefit him some in diminishing the protrusion, but hearing of the subcutaneous method of wiring the ring, he sought the services of a specialist in this direction, and six weeks later, after congratulating himself as well at last, the wire broke, severe pain and vomiting seized him, and I was summoned, with Drs. Minor and Hess, of this city, to reduce it. Taxis, which had previously always been successful, failed. Operation found groin full of cicatricial tissue, The scrotum was invaginated in the ring in placing the wire, which was found broken in three pieces and removed. Intestine and omentum returned and wound closed. Vomiting recurred and persisted; internal strangulation diagnosed, and laparotomy was apparently the only chance of saving life.

Dr. Edmund Andrews, of Chicago, was called into the case. Inguinal wound was opened up again, thinking a protrusion from vomiting, the after-effects of anæsthetic, might be the cause. Laparotomy was considered, but deferred. Vomiting again occurred, and persisted for three days, when irritability of stomach ceased and patient rapidly convalesced. Had operation been undertaken in first case, recovery would have been probable. Laparotomy in last case after the previous operations would likely have been fatal.

The deductions I wish to draw from these and other cases are as follows:

1. Strangulated hernia is not always easily diagnosed.

2. Operation is generally delayed too long. Many cases are allowed to die, and no operation undertaken for their relief by otherwise reputable surgeons, who magnify the dangers of the operation *per se*, which is criminal neglect.

3. What position, hot bath, and anæsthesia, with gentle taxis, will not accomplish in a very short time, had better be done by operation. Interference, and violent taxis, as often practiced, is condemnatory.

4. The Heaton method, and the plan adopted by some of wiring the ring subcutaneously, may be successful, but has not been so under my observation; yet it may deserve a more extended trial, for he who would devise some plan to permanently and safely relieve the ruptured would be a benefactor to mankind.

ACONITE POISONING.

BY M. STEWART, M. D.,
Of Vesta, Neb.

An interesting case of aconite poisoning came under my professional care recently, and I beg the privilege of reporting same, as it may prove of interest to some.

E. S. R., male, aged 50, of a naturally strong constitution, but still suffering from the effects of paralysis of left side about seven years ago. The shock to the nervous system was very great, especially to the pneumogastric of the left side, which, as a matter of course, seriously deranges the many organs which it supplies. His dyspnœa at times is very great, as a result of irritability of heart and organs of respiration. At time of the following event, he was just recovering from an aggravated attack of his heart and lung complication.

On the morning of March 29, thinking he had caught cold, he requested to be given a vial containing tr. aconite, that he might break it up, as he thought; but, having only a vague idea of the strength of the drug, he took nearly a teaspoonful. In about fifteen minutes he began vomiting severely, having a terrible nausea and constriction of the fauces.

In about half an hour I arrived, and attempted to administer an antidote per orem, but found it impossible to get him to swallow anything, let alone retain it. The pulse at wrist could not be felt, and during the act of vomiting he would sink into an unconscious state, with a partial rigidity of all the voluntary muscles. He would remain in this condition from a few seconds to as many minutes, during which all heart action would apparently cease; then he would revive, to again relapse when the exhaustion attendant upon acts of vomiting was repeated. At this time the pupils were largely dilated, great incontinence of urine, speech of a thick, husky character, and restlessness very great, no position being satisfactory for two consecutive seconds.

I then injected a drachm of fl. ext. of digitalis in his arm, and continued every half hour the alternate injection of the digitalis

with whisky and carbonate of ammonia. In about three hours the pupils began to contract, and vomiting and nausea were diminished somewhat, but dyspnœa and constriction of fauces continued to be very alarming.

In about five hours from time of taking he was able to sleep a little, and began to recover rapidly, with occasional attacks of nausea and vomiting. He made a quick recovery, next day being able to sit up and take a good meal with the rest of the family, and no bad results are left, with the exception of an ugly swelling resulting in a slough the size of a silver dollar, where the hypodermic syringe was used on his arm.

In connection with the weak, irregular heart which the patient has, the wonder is that a direct synergist to that condition like the poison did not completely paralyze the heart.

Medical Societies.

THE PHILADELPHIA NEUROLOGICAL SOCIETY.

(*Continued from page* 554.)

Stated meeting, December 28, 1885.

Dr. Guy Hinsdale presented a communication on

The Methods of Slaughtering Animals at the Philadelphia Abattoir.

There has recently been put in my hands a series of written questions which relate to the methods of slaughtering animals in our Philadelphia abattoir. The subject has been brought before the Society for the Prevention of Cruelty to Animals, and the officers of the Society desire to obtain from some of our Philadelphia physicians an expression of opinion as to the proper method of killing cattle with the minimum of pain.

As doubtless the members of this Society are aware, enormous numbers of cattle, sheep, and pigs, are slaughtered at the abattoir in West Philadelphia. Into the main half of the building, which is spacious, having a high roof, with good light and ventilation, the cattle are led in large numbers. They are apportioned to about fifteen different pens or iron cages arranged in a straight line, each capable of receiving seven or eight bullocks. The iron bars of which the cages are made are separated about fifteen inches from each other, affording a comparatively unobstructed view of the remainder of the room. The gate of exit from a pen is opposite the gate of entrance; above it is the windlass for hoisting. The animal is, in most instances, struck down while standing among his fellows, by a butcher who stands on a plank above him armed with a heavy, long-handled sledge-hammer. He is then hoisted by the windlass through the open door, is disemboweled, and dressed for the market within six feet of the animals remaining in the cage. When the carcass is ready for market one of the butchers climbs above the cage, and with the hammer strikes down two more animals; they are dragged out, and so on until all the animals are disposed of.

The Jewish butchers for ages have killed by bleeding. They never use a hammer, but after hoisting the animal by a hind leg, the throat is always cut by a rabbi or "shockem," armed with a keen sabre. This rabbi is detailed for duty at the abattoir.

Underneath the main hall is a cellar in which sheep and pigs are slaughtered by the knife. It is a dark, unclean, repulsive place. Large quantities of accumulated gore are seen in the places where the animals are usually killed. The surface drainage is very bad; the upper floor, though deluged with blood, is attractive in comparison.

The questions to which answers are desired by the Society for the Prevention of Cruelty to Animals are these:

1. Does the Israelitish method produce a total loss of sensation?

2. Does a total loss of sensation arise from a blow struck upon the head of the animal with sufficient force to knock him down?

3. What is the most humane way of slaughtering cattle, which would produce instantaneous death?

4. Do you think a bullock is so sensitive as to suffer terror or agony in witnessing the death-blows and sufferings of his companions?

With a view to satisfy myself on these points, I made three visits to the abattoir. I had no especial interest in the subject before, and supposed that the methods were not open to criticism.

As for the first question, I think it safe to say that the Israelitish method is instantaneous when once the steel strikes the neck. The blood gushes out, the brain is instantly deprived of blood, and consciousness is lost without appreciable loss of time. The young rabbi deserves credit for the skill with which he performs this operation. To suspend animals with heels up and head down is, at first sight, somewhat harsh, but, on the other hand, they are accustomed to a low position of the head, and the new position is only ninety degrees removed from the normal.

Regarding the second qnestion, it appeared to me that consciousness did not always cease when a blow was struck upon the head of an animal with sufficient force to knock him down.

The first two animals that I saw killed were struck on the head, in the middle line, a little anterior to the line of the insertion of the horns. They instantly dropped; a few convulsive movements, sometimes unilateral, sometimes general, occurred, and they were removed from the cage. The next three animals were struck by a different man. Two animals were struck eight times apiece, and the other nine times, before the butchers saw fit to proceed to dress the beef. Although the earlier blows were ineffectual, the later ones were delivered when the animals had lost sensation, and when the convulsive movements appeared too violent. In other instances one, two, three, or four blows were required. Animals were partially struck down, and did raise their heads and look about, unquestionably conscious of pain. The ox is not by any means the only animal that may preserve consciousness after being struck down by a blow upon the head. We ourselves may know this from personal experience. However, one blow well applied was sufficient, perhaps, in the majority of instances, to instantly destroy sensation.

Two other cattle which I saw killed at my third visit were attacked by a third man. The first received three blows upon the head, but still the animal walked about, and it became so difficult to induce him to stay still in proper position (the unreasonable creature!) that the butcher resolved to devote his attention to another animal, upon which, also, he delivered three heavy but ineffectual blows. I noticed by this time that the first animal was bleeding from the nose, and that both were able to walk about. This heavy hammer would sometimes bound from the skull as you might expect a wooden mallet to do. The animals gave no cry, and made no violent demonstration, as one might expect; they received these murderous blows as a prize-fighter might receive his, without evincing pain. They however, became uneasy, endeavored to avoid the man crouching above them, and, without much trouble, were finally dispatched. As to whether a bullock is so sensitive as to suffer terror or agony in witnessing the death-blows and sufferings of his companions, interesting metaphysical questions are involved. Butchers in the abattoir do not seem to think that the animals are conscious of their surroundings. They say they occasionally milk a cow in a cage near which animals are being slaughtered. It is quite evident that, as a rule, bullocks make no attempts, or the most ineffectual attempts, to avoid the fate of their companions. In one instance which came under my observation, the last of a series of bullocks became frightened; he dodged the blows, put his head through the bars, and held it low, out of the reach of the butcher standing on the top of the cage. Men with sticks poked him about, while inaccurate blows fell upon his head, until, after a disgusting struggle, he was dispatched. This animal seemed to me to act at the start as though he appreciated danger from witnessing the death of his companions. Butchers say that Texan steers give more trouble than others, and are more liable to grow wild at the sight and smell of blood. It cannot be that their mental powers are radically different from those of other varieties of oxen.

It is not necessary to repeat before this Society anecdotes or proofs to show that a steer may become frantic at the sight and smell of blood. Carnivorous animals are not so susceptible. A dog may even eat another dog, as one of our proverbs says, and yet some dogs are capable of sympathy, and exemplify it by appropriate behavior. Not only the elephant, but even so small a creature as the ant, manifests sympathy.* The sense and the understanding are the prerogative not exclusively of man. These lower animals have attention, memory, association. They exhibit generosity, gratitude, courage, caution, patience, industry, anger, and grief.

Doubtless the ox or the sheep or the pig cannot claim the possession of all these qualities. But their mental system is much less perfectly understood than ours. "The popular tendency has been to underrate the acquired knowledge of animals, if not to ignore it altogether. At present we are not in a condition to dogmatize, owing to the want of proper observations on the whole department of brute intelligence."† As Lander Lindsay puts it, "the very terms animality and humanity are, on the one hand, unnecessary distinctions; while, on the other, they are generally wrongly applied, for there is more animality in man and humanity in animals than our self-conceit will permit us willingly to recognize. We cannot correctly speak of the animal in contradistinction to the human mind, inasmuch as mind is essentially the same in other animals as in man, differing simply in the degree of its development and the mode of its expression."‡

* Romanes, Animal Intelligence, p. 47.
† Art. Instinct, Chambers's Encyclop.
‡ Journal of Mental Science, April, 1871.

But what can be done to remove the objectionable features of this necessary work of slaughter?

In the first place, the work of killing these animals should be given only to a man of experience and power.

2. It is not necessary, and it should not be permitted, that animals should witness the death of their fellows. They may wait their turn together, but finally should be led to an apartment alone, where a single successful death-blow may be given.

3. Means should be provided for making this blow unerring. A crushing blow on the brain-case is, undoubtedly, a painless death, and, by a mechanical contrivance, this might be made unfailing. Fixation of the head would be necessary, and perhaps could be accomplished by means of the horns. An experienced executioner, with an adequate instrument, either in his own hands or under his control, as a trip-hammer is under the control of a forger, would then dispatch these poor brutes with the minimum of pain.

4. The number of men who perform this work should be small; and boys, women, and the public generally, should not be permitted to witness these brutalizing scenes.

5. The Jewish method, when rapidly performed, is, on the whole, not a cruel method.

6. The city should take immediate steps to supervise this abattoir; it should have an official inspector of meat, and adopt some effectual scientific method for the detection and condemnation of diseased meat.

If this Society will endorse these statements, I believe that a better state of things can be secured. If proper evidence can be adduced, the Society for the Prevention of Cruelty to Animals will take hold of the matter, and insist on reform in this important public institution.

Dr. Charles K. Mills moved that a committee be appointed to visit the abattoir, and report to the Society on the questions proposed by the Society for the Prevention of Cruelty to Animals.

The committee consisted of Drs. H. C. Wood, H. A. Hare, F. X. Dercum, A. P. Brubaker, and Guy Hinsdale.

Stated meeting, January 26, 1886.

Dr. John H. Musser presented some

Notes on Thirteen Cases of Tubercular Meningitis. (*See page* 591.)

Dr. William Osler then read a paper on

The Structure of Certain Gliomata.

He desired to call attention to the histological character of certain brain tumors which present peculiarities of structure separating them from the ordinary small-celled gliomata.

The specimens which he showed were from three cases, the features, clinical and anatomical, of which may be thus summarized:

Case I. Girl aged sixteen, blind from third year; intelligent; head not large. Occasional convulsions and spasms of muscle of neck. Death sudden. Tumor occupied the surface of the left thalamus, and extended into the third ventricle. There was extensive dilatation of the lateral ventricles.

Case II. Girl aged fifteen. Jacksonian epilepsy for over fourteen years. Small, firm tumor occupied the upper part of ascending convolution.

Case III. Man aged forty. Head pain, mental disturbance, drowsiness, the chief symptoms. Tumor, the size of a lemon, occupied left anterior lobe of brain.

The physical characters of these three tumors differed considerably. In case I. the mass on the thalamus was firm, but the portion projecting into the third ventricle was soft, grayish in color, and looked like an actively growing neoplasm. In Case II. the small tumor at the upper part of ascending frontal convolution resembled a patch of sclerosis; while in Case III. the tumor had a large central area of fibro-caseous change, with a peripheral zone of actively-growing grayish-red tissue.

Histologically these tumors are similar in the dense feltwork of fibres which make up the chief mass of each, the fibres varying somewhat in thickness and in closeness of arrangement. Careful observation of teased specimens shows that the fibres are, for the most part, in connection with cells, and so far the growths conform to the type of glioma. True, we do not find here the typical arrangement of small cells with delicate protoplasm and numerous fine ramifying processes, which gives to many gliomas an appearance not unlike that of a small-celled sarcoma. There are gliomata, however, with larger and more irregular cells, and with coarser fibres than the description in textbooks would lead us to suppose, and it was to certain characters in the cells of these tumors that he wished to call attention. A study of teased, fresh specimens can alone give a clear idea of the shape, size, and relations of the cell elements.

The following varieties of cells occur in these growths:

1. The ordinary "spinnen," or spider cell, with many processes, and which may be regarded as the characteristic cell of the glioma. These present a considerable variation in size; many are not larger than colorless

blood corpuscles, others double or treble the size. The smaller have more delicate processes which in sections of hardened specimens may not be apparent. Some of the larger of the cells look not unlike multipolar nerve cells.

2. Large, unbranched, spindle-shaped cells, with greatly elongated processes. These resemble enormous connective tissue corpuscles, and the processes may be traced until they taper to extremely fine fibrils. Others are scarcely spindle-shaped, but present flat, ribbon-like processes. Some of these cells are among the largest and most remarkable met with in tumors. In Case 1, the mass in the third ventricle was composed largely of them, and isolated ones measured as much as 0.4130 of a millimetre. They present usually single large nuclei, and the protoplasm of the cell is either homogeneous or finely granular. In Case 3 these forms were also very abundant, but in Case 2 they were not numerous.

3. Cells which resemble closely in appearance large ganglion cells of the nerve centres. They present a dark granular protoplasm, large nuclei, and one, two, or more processes, which either run singly or finally branch. The most remarkable-looking are those with a single process springing from a balloon-shaped cell. Others have a process from either end of the cell body. They are usually much larger than the spider cells.

4. In Cases I. and III. there were structures of very curious aspect, which probably may be regarded as derivatives of the large fusiform-shaped corpuscles. These were remarkably translucent, band-like fibres, tapering slightly at either end, but without nucleus or granular protoplasm. From their close resemblance in form to the spindle-shaped cells, and from the fact that these latter often present a remarkable translucency, I think we may regard these peculiar fibres as resulting from a vitreous or hyaline transformation of the large spindle cells.

These tumors conform to the variety described as neuro-glioma by Klebs, who holds that the large ganglion-like cells found as such important constituents of these growths are derived directly from the nerve cells of the gray matter, and that in the development of this variety all the elements of the nerve tissue participate. Certainly the resemblance between many of the large cells and nerve elements is very striking, but I have not been able to satisfy myself of their relation to the pre-existing tissue parts. This is, of course, extremely difficult, but in a careful study of sections taken from the advancing regions of the growths, I have not met with appearances which would lead me to suppose that the nerve cells were in process of proliferation. Klebs states that he has demonstrated by means of osmic acid and gold chloride the nature of the cells and their processes, but this has not been confirmed, and I could not determine that the cells or fibres described above behaved in a characteristic manner with these reagents. That they are probably connective tissue elements seems probable from an examination of a large number of the cells in teased preparations. Gradations and intermediate forms can be seen between cells closely resembling unipolar or bipolar nerve ganglia and the typical spider cells with innumerable processes. Gliomata of this form are not uncommon. Klebs described fourteen or fifteen, and of five cerebral tumors of the glioma type which I have met with, only two were of the small-celled variety.

Dr. Wharton Sinkler reported

A Case of Brain Tumor.

Miss S., æt. fifty-two. Mother, maternal grandfather, great grandfather, two maternal uncles, and two brothers died of phthisis. Paternal ancestors long-lived. No cancer. Healthy and well up to four years old. Then had a serious illness spoken of by some as "brain fever;" another person says dysentery. Seemed to recover entirely from this, and was bright, well, and agreeable. Was not very intelligent mentally, but not by any means deficient. Catamenia first appeared at eighteen years. At seventeen years friends noticed a change in her; she was irritable, cross, and peculiar about many things. This condition of things continued through the remainder of her life, all the peculiarities becoming intensified. She was a great reader and a great eater. She was fond of literary pursuits, and spent a considerable amount of time in writing and painstaking composition. She never had convulsions as far as known. At twenty-five years she was examined as to her mental condition by Dr. Wm. Kirkbride, and he decided that, although not mentally vigorous, she was not insane.

For five or six years before her death, say forty-five years of age, she seemed to grow stouter, less inclined to work, and in walking seemed to move slowly and with difficulty. For three or four years before her death there was a drooping of the left corner of her mouth, most noticeable in smiling or speaking. This gradually increased. For eight or ten years she has had headaches.

In the summer of 1885, she was at Atlan-

tic City and had two or three attacks of violent headache associated with unconsciousness. These lasted several days at a time. She came under my charge in September, 1885. She then showed slight left facial paralysis, but no loss of power in arm or leg of either side. She complained sometimes of pain in the head, sometimes in the shoulder or neck. Seldom seemed to have persistent pain in one place. She had an attack of unconsciousness with severe headache. Screamed with pain, but could check herself, and when asked what was the matter said she had pain, but could not state exactly where it was. At times she talked incoherently, and spoke of having seen persons whom I knew she had never seen. She was unwilling to leave her bed, but if she could be persuaded to get up, could walk about. Her appetite was good, but there were indigestion and constipation. No vomiting. Vision seemed good, but the eye-ground was not examined. She was eccentric in her way of talking, and said many things with the evident intention of creating surprise.

At my suggestion, she was taken to a country town in the vicinity of Philadelphia and was there under the care of Dr. J. Reeve. After reaching this place she complained of pain in the right side of the head and seemed unable to walk. Would fall into a semi-unconscious condition which would last for some hours. The temperature became elevated. The facial paralysis became more marked, but although no paralysis of the limbs there was general muscular weakness. The patient died on October 26, 1885.

The post-mortem examination was made by Dr. H. R. Wharton. Brain and cranial cavity: Upon exposing the membranes of the brain they were found markedly congested, and the dura mater was very adherent to the petrous portion of the temporal bone on the right side. Brain removed, membranes divided and turned aside. Upon left side there was no apparent lesion. On the right side some bulging of the membranes was apparent in the region of the fissure of Silvius, and upon dissecting them off they were found very adherent to a tumor larger than an English walnut, growing from the fissure of Silvius about the line of the fissure of Rolando. The tumor was dead red in color, stood out from the brain tissue, and was dense to the touch. There was some effusion in to the ventricles.

Dr. de Schweinitz made a microscopic examination of the growth, and sent me the following report:

"The small portion sent for examination was hardened first in a solution composed of Müller's fluid one part, and methylic spirit three parts, for six weeks, and then in alcohol. Sections were cut, stained with carmine, and mounted in balsam. In the periphery the growth shows a structure composed of more or less perfectly developed fibrous tissue; more interiorly the stroma of the tumor is made up of numerous, varously sized, dilated blood-vessels, sometimes empty, but for the most part filled with corpuscles. Between these are numerous small round and large spindle cells (sarcoma tissue) scattered through the growth, sometimes singly, often in groups; they are round, yellowish-white bodies, which are probably amyloid in their nature. The tumor may be properly classed as an *angio-sarcoma.*"

The growth, as may be seen, is spherical in shape and springs up out of the fissure of Silvius. The points of interest in the case to me are these: First, the probable long-standing of the growth. It is likely that it began at the age of eighteen years, when mental peculiarities first showed themselves. Secondly, the absence of most of the symptoms peculiar to brain tumor. There were no convulsions, no vomiting, no defects of vision, and no pain localized in one particular spot. The facial paralysis was not noticed until three or four years before death.

There were many marked hysterical symptoms which masked the true nature of the disease. These, I think, are often met with in brain tumors in women.

Dr. H. C. Wood reported

Two Cases of Syphilitic Disease, the Lesion in One Involving the Ascending Frontal Convolution; in the Other, the Cervical Spinal Cord.

The first of these cases is of a special interest, because so far as the motor symptoms are concerned, the situation of the lesion closely agrees with the modern doctrine of cerebral localization, whilst no lesion was found to account for the loss of sensibility. The only explanation that could be given of this is that disease had existed in the membrane over the angular gyrus, and had been removed under the influence of the mercury, there being no record as to the condition of sensation just previous to death. This explanation seems, however, rather lame, because more distinct traces of such lesion would naturally be expected. The cases are also of interest as illustrating a danger which always overhangs a person suffering from syphilitic epilepsy—namely, possible arrest of respiration during the convulsion, and consequent death.

Case I. R. B., male, aged fifty, entered the Nervous Ward of the Philadelphia Hospital, January 2, 1885. The following extract is taken from the case-books of the institution: "R. B. says that his health has always been good, and whilst acknowledging that he had chancres twenty-five years ago, denies all other forms of venereal disease. Eight years ago he fell downstairs and struck his forehead just above his left eyebrow; he was picked up unconscious, and remained in that condition for four hours. One week after his fall he returned to work, but was troubled with a feeling of lightness in his head and vertigo. About two weeks after this he suddenly felt a peculiar pricking sensation in his right foot, which extended rapidly up the leg to the thigh, and finally to the right arm, and thence to the head, and was immediately followed by unconsciousness. He has never bitten his tongue in this or any subsequent attacks. The convulsion was followed by a period of stupor or sleep. About two weeks after, there was a second epileptic attack without any aura or other warning. His arm, which had continued in a numb condition ever since his fall, for a time grew steadily worse. For one year its condition then remained unchanged. He still had epileptic attacks at intervals varying from a few weeks to a few months. Eighteen months ago he had an apoplectic attack, in which the unconsciousness lasted for several hours. There was no ensuing paralysis; nor did his health seem to be the worse for the sickness. He states that he now has at about monthly intervals attacks of epilepsy. These attacks are preceded by a peculiar twisting of the fingers of the affected hand, and followed by stupor or somnolence, lasting for about twelve hours.

Present Condition.—There is partial motor paralysis of the right hand and arm. With the left hand he moves the hand of the dynamometer to 95; with the right only to 30. The æsthesiometer points, separated to their widest, are felt on the right hand and arm only as one; on the left arm the points are separated on the ulnar and radial side at two and a half centimetres apart; on the palmar surface at four centimetres. He has not as good use of his left leg as formerly, although there is no complete paralysis of any of its muscles. Patella tendon reflexes normal. Ordered potass. iodide in ascending doses.

Treatment.—January 6, 1885. According to statement of nurse, in his fits the patient works altogether with right side. Left pupil slightly smaller than right. Perceptible weakness in right face. Dynamometer: right hand, 46; left hand, 87. In neither thigh is there any difference in sensitiveness. He complains a good deal of frontal headache. Edges of the optic disks sharply cut, and optic disk itself abnormally white, believed to be atrophic. Ordered to be ptyalized.

The patient was ptyalized, and afterward was given the iodide very freely; but notwithstanding there was distinct improvement in regard to headache and general condition, the fits continued, although at longer intervals, and on the ninth of May there was prolonged unconsciousness after a fit, ending in death.

Autopsy.—Contents of thorax normal, except as to congestion; liver is large and congested, indurated, capsule thickened. In the tissue between the right and left lobes, anteriorly and near the lower edge, is a distinct gummous tumor of the size of a hickory-nut. The new growth has developed from the capsule and grown inward. Upon the upper border of the same fissure and posteriorly is a scar, evidently a healed gumma. Kidneys congested, but otherwise normal. Rest of organs normal.

Brain.—When the skull-cap was removed some ounces of black blood ran out. Membranes much congested everywhere. Dura mater normal, except in being abnormally adherent to the edges of the great fissure.

Left Hemisphere.—Arachnoid and pia mater abnormally thick, especially superiorly, and somewhat opaque. Vessels somewhat congested. On external inspection of the bared convolutions, nothing abnormal is observed, except about the middle of the ascending frontal convolution, where at a spot one-half inch in diameter the membranes were fused with the brain surface, and could not be separated. The tumor is one-third of an inch in thickness, and in tearing it out a definite cavity was left. No other lesion discoverable in any part of that hemisphere. Remainder of brain normal in general structure.

Cause of Death.—Edema of the brain from cerebral syphilis.

Case 2. Cadamoni, aged about twenty-two, entered the wards of the Philadelphia Hospital, June 1, 1885. As he was an Italian of very low order of intelligence, no detailed history of his case could be obtained. He stated, however, that he had been well and strong until three months before, when he had been hurt in the upper part of the back, and had not been able to work since. One month before entrance he had rapidly lost power in both arms.

His condition at the time of entrance to the hospital was as follows: He was unable to stand, and entirely confined to bed, but can make feeble and slow movements of the thighs, legs, and feet; all muscles seeming to be about equally implicated. The whole of the left arm is paralyzed, except the thumb, which can be moved slightly. In the right arm the deltoid and the flexors of the fingers are much wasted. There is no paralysis of the face; patient cannot turn in bed, but has not lost control of the bladder and of the rectum; sensation is not much affected; pain is complained of in the back and side of the neck and in the limbs, especially in the arms; marked pain in the sternal region on coughing. Pressure of the lower cervical vertebræ causes severe pain, and forcible jarring of the head also produces pain in the lower cervical spine; cervical vertebræ not distinctly prominent; patella reflex somewhat exaggerated; temperature normal; bowels persistently very costive.

The patient was put upon a water bed; iodide of potassium given in rapidly increasing doses, until a hundred and eighty grains a day were taken; but the symptoms gradually increased, paralysis became more marked in the lower extremities, and complete in the arms; power over the bladder and rectum was lost, and the patient died June 18th, seventeen days after his entrance into the hospital.

The autopsy was confined to the vertebral tract. In the lower cervical region, extending into upper dorsal, was a thickened mass, several inches long, not at all separable from the membranes of the cord. The outer portion of this is formed of a uniform structureless base, filled with numerous long, narrow, curved cells, evidently derived from connective tissue. Within this, the mass is chiefly composed of innumerable small, round, closely-packed cells; sometimes arranged in irregular, diffused masses, but in many cases collected into globular masses, which are only in rare cases distinctly separated from surrounding tissue. A few of these masses were yellow, the cells evidently undergoing fatty degeneration, and not taking staining at all.

Cord underneath the tumor chiefly composed of a structureless, minutely granular, neuroglia matter, with numerous roundish neuroglia cells. No nerve tubule discoverable in section. Gray matter affected nearly as much as white: ganglionic cells still present, although most of them much altered.

The following report was made by the committee appointed to inquire into the

Methods of Slaughtering Cattle,

and the question as to whether cattle suffer from witnessing the slaughtering of companions:

Your committee have the honor to report that they held a meeting at the Philadelphia abattoir, and witnessed the slaughter of a number of cattle. As the arrangement of the building and the methods employed have been fully described to the Society in the paper of Dr. Hinsdale, it does not seem necessary for your committee again to go over this ground; and the committee confine their report to answering the questions proposed by the Society for the Prevention of Cruelty to Animals. We find, in the first place, that, owing to the unskillfulness in the use of the hammer by the butchers, perhaps in the majority, certainly in a very large proportion of the casee, the animal is not rendered permanently unconscious by the first blow. In a number of instances, the creature when struck either failed to fall, or simply went down upon his knees and rose again, and had to be driven around the pen, and sometimes struck again and again before falling. Further, it is the habit of the place to strike down several bullocks one after the other, so that one or two of the animals must lie on the ground some time before the throat is cut. In very many instances the creature seems partially to recover its senses during this time, and in some cases undoubtedly becomes perfectly conscious, and even gets upon his feet. There can be no doubt, therefore, that a large amount of unnecessary suffering is produced in the killing as practiced at the Philadelphia abattoir.

A properly directed and sufficiently powerful blow undoubtedly will immediately put an end to consciousness. It is not the general idea of the method of killing which is at fault at our abattoir so much as the unskillful way in which it is performed. If the animal were driven into a narrow pen, so as to insure quiet and a perfect opportunity for a blow; and if, at the same time, the hammer were heavier than the one now used, and were only employed by a skillful person, nothing more could be desired. In our opinion, there should be one man whose sole duty it is to strike down the animals, since only by repetition can perfect skill be required.

We believe that there is a certain amount of psychical suffering induced by the present method. The animals evidently have a sense of danger, although they apparently do not recognize the point from which the danger is coming. The need for the appointment of some one who shall inspect the carcasses of

the slaughtered animals was very well shown by the fact that, in one of the beasts killed during our stay, the liver was full of hardened nodules of a whitish color, and many of the lymphatic glands were evidently affected with the same disease. So far as gross appearances could determine, the animal, when killed, was in the advanced stages of tubercular disease of the liver. The nodules have been referred for examination to well-known microscopists, whose report we hope to hand in accompanying our own.

After the reading of the report of the Committee, on motion it was accepted, and the Committee were requested to present the matter, on behalf of the Neurological Society, to the College of Physicians of Philadelphia.

Notes of Thirteen Cases of Tubercular Meningitis.

By J. H. Musser, M. D., Physician to the Philadelphia Hospital.

All of the cases were observed in private practice, hence the lack of detail of symptoms, such as temperature, etc. They occurred in a period of six years. Nine of them were in the writer's private practice, two in institutions under his care, and two in the practice of medical friends. It may be considered a disease of frequent occurrence, for the relative proportion of its frequency to that of many other diseases, as forms of liver disease, is much in excess. The nine cases occurred in a practice ranging from 50 to 400 families yearly, during the six years. For every case of tubercular meningitis, the writer has had twenty-five of phthisis. During the same period one case each of tubercular peritonitis and interstitial tuberculosis have been under his care. In later years the disease has been less frequently seen, corresponding with the social improvement of the practice. In the first half, six cases were observed. In the latter half, the remaining ones. The mortality table of the "Homes" to which the writer has been physician, present some very interesting features in this connection. In one Home of 180 boys, aged from three to sixteen, and 30 adults, but three cases of tubercular meningitis occurred in five years. In a Home for 24 colored children of both sexes, mean age seven years, the disease was not observed in four years. In a third Home for children of both sexes, about eighty in number, in the records of twelve years, no death occurred from this disease. During the same period of observation of these nine cases, five cases of hydrocephaloid disease, one of cerebro-spinal meningitis, and two of syphilitic meningitis, were observed.

Causes.—Seven of the cases were males, and six females, making six of no causal influence. The ages ranged from seven months to fourteen years in twelve cases. One was thirty-two. Six of the patients were under five years, four between five and ten, and two between ten and fifteen. The ancestors of nine had tuberculosis in some form. In two other instances the children of the same generation had some tubercular affection. In only two cases was there no antecedent or coincident history of tuberculosis in the family. One of the patients, aged seven months, was nursed by a mother whose tubercular disease antedated her pregnancy.

The hygienic surroundings in the large number of cases were quite fair. Two alone could be pronounced as bad. One child had been weaned early in life, and improperly fed. The previous health of all save one or two was bad. Some remote local inflammatory foci, either of simple or specific nature, could be determined. In one, aged fifteen months, the bronchial and mesenteric glands, after a whooping-cough or diarrhœa, were diseased; asthma and bronchitis, with enlarged bronchial glands, no doubt, preceded in another; hip-joint disease, suppurating cervical lymphatics, chronic bronchitis, and phthisis, respectively, preceded in four cases. Very poor health in one instance, and "weak" lungs in another, also preceded. In one, the health had apparently been good; in two the state of the health was not noted. Exposure to the sun was thought to be the cause of the twelfth, but the lad was always fragile, and had diarrhœas. The nursing baby completes the list—she was always delicate.

Clinical Course.—In general, it may be said to be irregular. In six cases the periods of invasion, excitation, and depression could be traced. In two instances the stage of invasion, or the premonitory symptoms, was absent entirely. In the other cases the stages were "mixed."

The following summary indicates the mode of development of the entire series. Case 1 was a girl aged sixteen months; antecedent cause, whooping cough and tabes mesenterica; slight general spasm, followed in a few hours by convulsion of right side of body, with aphasia. In case 2, boy aged four, with asthma, etc., there was loss of flesh for four weeks, intermitting headache ten days, vertigo three days, was peevish and restless at night. Case 3, girl aged ten years, had for one year headache and vertigo, extreme emaciation, cerebellar tumor.

In Case 4, there were loss of flesh, debility, restlessness, and poor appetite for several weeks. The course of the fifth was not known, while the sixth had been ill ten days definitely; for a brief time loss of flesh with pain in the left temple, sleeplessness, and constipation had been present. Sharp paroxysmal headache tormented the seventh case, a youth of nine, for three days prior to the meningitic explosion. Until twenty-four hours before very active symptoms occurred, the eighth case, an infant under two years, was considered in perfect health. Prolonged lassitude, fretfulness, and some emaciation, preceded the illness of Case 9, a boy of eight. For four weeks the tenth case, a precocious little girl five years old, suffered from symptoms not unlike malaria — languor, emaciation, fretfulness, irregular intermitting fever, restlessness at night, poor appetite, without vomiting or constipation. The eleventh case had phthisis, but observed that his customary hectic had quitted him two weeks before the development of headache and vertigo, which symptoms antedated the active brain symptoms by four days. The twelfth case did not thrive as a nursing baby should, and vomited frequently. A convulsion was the first warning of cerebral trouble. A little girl, lost appetite, was peevish, slept poorly, was feverish, and became emaciated for threeweeks before the cerebral symptoms developed. She had lymphatic enlargement in the neck and abdomen. Emaciation, debility, fretfulness, night-restlessness, irregular febrile movement, disorders of the gastro-intestinal tract, and headache, therefore, were the chief premonitory symptoms. Emaciation, it is seen, was the most frequent and most marked.

An analysis of the phenomena of the first and second stages would be tedious and without practical value. Reference in the succeeding notes will be made to some salient groups of symptoms, present more or less in both stages, and to peculiar manifestations of common symptoms. *Headache*, *motor*, and *sensory irritations*, and *palsies*, occurred in all the cases. In a few, the *headache* was distinctly intermitting. The *spasms* and *palsies* of groups of muscles were irregular in respective cases, as to order or frequency. Hourly change in the state of the muscles was common, and the same may be said regarding sensation. Not only does this apply to alterations of function of spinal, but also of cerebral nerves. Convulsions (partial, unilateral, or general), delirium, and coma were present at the present period, but presented no peculiar feature.

Special Senses.—Total blindness was observed in one case; impairment of vision in five; optic neuritis was recorded in three. The state of the pupils was not of special import—in one instance was there irregularity in size in the second stage. In the first stage they were not affected, save contracted in one instance, and fixed, in a dilated state, in another. Dilatation was the rule in the second stage. Nystagmus was observed in one case. Purulent conjuctivitis occurred in eight cases, in the second stage usually, and in two instances was unilateral. Ptosis was present in only one case.

In five instances local erythema and general flushings were noted. An urticaria-like rash was seen in three instances. In the later stages pallor or a bluish hue of the face was observed. A unilateral mottling of the extremities was observed. Emaciation was marked and persistent in the prolonged cases, nine in all. Fever was present in the first stage in seven cases; in the second, in nine; intermitting in type, often with irregular paroxysms. Hyperpyrexia was noted in one. The *pulse* was slow seven times in the first stage; irregular or intermitting in four. In the second stage it was usually quickened, small, rapid, and feeble; twice, slow and irregular. It was never wiry or corded in either stage.

Vomiting occurred but three times in the first stage; once only in the premonitory stage; and once only in the final stage. Constipation was seldom observed—three times in the first, twice in the second stage. Diarrhœa was excessive once. Offensiveness of the *breath* was very frequent, and occurred chiefly in the last stage, but was so marked at first, also, in three cases, as to be noted. In the larger (nine) number of instances the tongue was heavily coated. The scaphoid abdomen occurred at varying periods; once in the first stage, seven times in the second stage, while three times it is recorded absent; twice there is no record.

Respiratory symptoms.—First stage, irregular or Cheyne-Stokes, four times, rapid twice, slow once. Second stage, Cheyne-Stokes twice, rapid six times.

Remissions of a decided character were noted twice; after the development of the most grave symptoms, a period of improvement led to hopes of recovery.

Duration.—Of premonitory symptoms, unknown twice; prolonged, once; one year, once (tumor); in two cases, about four weeks; in two, ten days; in one each, three days and twenty-four hours; in two they were absent; and in two the first stage developed at once.

First Stage.—Twelve hours, 2; four days, 2; five days, 2; ten days, 2; eleven days, 1; thirteen days, 1; unknown 3.

Second Stage. — Twenty-four hours, 1; seven days, 1; five days, 3; forty-eight hours, 1; six days, 1; eight days, 1; four days, 2; nine days, 1; unknown, 2.

Entire Duration.—Thirty-six hours, 1; four days, 1; seven days, 1; twelve days, 2; fifteen days, 2; eight days, 1; fourteen days, 1; eleven days, 1; unknown, 3.

The difficulty of estimating the duration is evident to any one. It can only be said that a short first stage, in all the instances, determined a short second stage.

A post-mortem examination was held on four of the cases. In two the disease was largely localized, once in the cerebellar region, in another over the right frontal convolutions, the presence of the tubercle causing during life the symptoms due to localized cerebral irritation at these points. The autopsy also revealed in the case of aphasia, etc., a well-known rule, that the amount of gross lesion is not to be inferred from the extent of symptoms.

Summary.—Tubercular meningitis may be considered a disease, (1) of frequent occurrence in the middle and lower classes especially; (2) more common than other localizations of tuberculosis, except the pulmonary, and much more frequent than other varieties of meningitis. Among the *causes* most prominent are age, hereditary predisposition to tuberculosis, poor hygienic surroundings, and insufficient and poor food.

The prime factor always to be looked for is the presence of a primary focus, inflammatory, tuberculous, or "cheesy." The important symptoms presented in this series of cases were, in addition to the usually noted ones, in the premonitory stages; emaciation, irregular fever, and gastro-intestinal disorder without vomiting; in the succeeding stages, purulent conjunctivitis, erythemas, and other vascular changes in the skin, excessive emaciation, fever, offensiveness of breath, the caphoid abdomen, and changes in respiraory rhythm.

Periscope.

Hernia Cerebri Successfully Treated by Closing the Opening in the Skull with a Silver Plate.

Before the Clinical Society of London, Dr. Roderick Maclaren read an account of this case:

A man, A. N., aged 26, was admitted to the Cumberland Infirmary, on March 25, 1885, with a compound fracture of the skull inflicted three days before. For six days after his admission, his condition grew progressively worse. He became deeply comatose, passed motions involuntarily, and had frequent convulsive attacks. The scalp-wound was then enlarged, and all fragments of bone removed; they were ten in number, some being deep in the brain substance. The aperture left in the skull was three inches long, and varied in breadth from one inch above to half an inch below; it was three-quarters of an inch in front of and parallel to the left temporal ridge, and its lower end was at the supra-orbital ridge. Some brain which had protruded was removed, and some diffluent blood gently syringed away. While he was being put under chloroform, it was noticed that the right side was paralyzed. An attempt was made to make the wound aseptic; this failed. From this time his condition improved; he gradually became less comatose, convulsions ceased, and in about a fortnight he understood what was said to him, though he did not speak. By this time, hernia cerebri had again occurred, and Dr. Maclaren removed it, placing a silver plate (a rolled-out florin) inside the skull, so as to block the opening, This was done on April 14; by May 3, the hernia cerebri again existed, owing to the plate slipping to one side within the skull. The protrusion was cut off, and this time the plate was so secured with suture-wire that it could not be thrust to one side. The scalp was liberated by two incisions parallel to the wound, and sutured over the plate. The plate was left in for two months; no protrusion occurred when it was removed, and the wound soon healed. He was discharged from the hospital on September 5. His condition was slight dragging of the right leg, absolute paralysis of the right arm, and slight want of expression on the right side of the face. His speech was well restored, though he was sometimes at a loss for a word, and much given to repeat the same expressions. During the latter part of his stay in the hospital, he had two fits, and he had had

several since, mostly at night, and always with an aura. The paper pointed out the very small amount of local irritation caused by the plate, and that it did not exercise any pressure on the brain, but merely replaced the normal case; and that the result was a substantial reason for trying it again in a similar condition.

The President thought congratulations were due to Dr. Maclaren on the result of his treatment. Cases of the kind were difficult to treat. The plan adopted was novel; but he (the President) was not disposed to think that it was very superior to that of external pressure by thick sheet-lead. The hernia should be kept down by pressure. He had a great objection to the slicing away of brain-tissue, although the symptoms following such an operation were not generally very prominent. He would ask Dr. Maclaren why he had sliced away the protruding brain; why he had not instead thereof applied something like powdered oxide of zinc, which withered up the parts.

Mr. Golding-Bird had had two cases; one five or six years ago, in which, after trephining, the patient had done well, although he had had hernia cerebri as large as a walnut. Tannic acid being applied, the protrusion withered, and he was now quite well. On the other hand, another patient, a boy, had hernia cerebri after an accident, with no objective symptoms of paralysis, nor change of any kind in his sight or mental condition. Tannic acid being applied to the hernia, he had cerebritis, and died; and it was afterwards found that he had sloughing of the protruding brain, which sloughing extended to the lateral ventricle. In a third case, an abscess was evacuated, an antiseptic lotion applied to the hernia cerebri under external pressure, and the patient in the main recovered, though he had some slight paralytic symptoms. If in Dr. Maclaren's case pressure, external to the skull, had been applied to the tumor, Mr. Golding-Bird believed the patient would have done as well. He would ask, if eventually the patient quite recovered his mental functions.

Mr. Pearce Gould had treated one case of small protrusion by external pressure with lint, without making any impression on it. Although part of a motor tract was protruding, there were no paralytic symptoms. One day, the patient had a fit. Mr. Gould then shaved off the hernia, and opened an abscess in the brain beneath. The boy recovered, although he had at first slight paralysis of the fact on the opposite side. It must not be forgotten that hernia cerebri was of various kinds. In his own case, whilst suppuration was going on in the brain beneath, pressure on the hernia failed to do good. One should not look so much to the external application as to the condition of the brain below, on which he thought the result of the treatment rather depended.

Dr. Maclaren, in his reply, said that in his case external pressure of various kinds had been tried, and yet the brain, in spite of it all, protruded. The brain, in protruding, was opened out by the inflammation of its substance; so that, when it was sliced off, not so much of real brain-tissue was removed as one would at first suppose. A parallel case was that of fungating testicle. The man's intellectual faculties had never been of a brilliant character, and his language was Gaelic, so that it was difficult to judge if his mental functions were impaired.

A Case of Stramonium Poisoning with Peculiar Symptoms.

Dr. C. C. Gratiot thus writes in the *Association Journal:*

Between the hours of 7 and 8 p. m., on February 22, I was called in haste to see the child of Street Commissioner Thomas Lee, of Shullsburg, the messenger stating that the child was having convulsions. I arrived at the house within a few moments and found the patient, a boy three years of age, sitting in his mother's lap, his arms and hands outstretched as though to grasp some object. He would open and shut his fingers with deliberation, as though the object he was trying to grasp required some caution and skill to take hold of. After two or three minutes of such manœuvering he would make a sudden jump as though about to seize the object, and would then cry distressfully.

While his hands were thus employed his eyes were fixed, looking straight ahead as though watching something. The pupils were widely dilated, cheeks flushed, mouth dry, pulse fast and full, heart's action good but fast, and respirations increased.

There was also another hallucination. He would act as though something was approaching him from the opposite side of the room, and would point towards it; his eyes and facial expression would convey the idea that the object was after him, and coming nearer and nearer, until he became so agitated that he seemed on the point of having a convulsion.

These hallucinations would alternate, and the only thing that diverted his attention for an instant would be to offer him a cup of

water, which he took with a seeming relish. Turning down the light until the room was almost dark made no difference in his actions.

I was told by the parents that he had always been healthy; that he had been playing out of doors all day, ate a hearty supper, and that nothing wrong was noticed until a few moments before they sent for me, when he commenced to act in the manner described. I inquired if there was any medicine in the place that he could have taken, but could find nothing that threw any light on the case. While watching him and making these inquiries, I noticed that the symptoms were getting worse.

It occurred to me that the symptoms were those of belladonna poisoning. I administered an emetic of ipecac, gr. x., and a large quantity of water. He vomited in a short time, but there was nothing unusual in the ejected matters. I then gave small doses of morphia and bromide of potassium, and rectal injections to move the bowels, but without effect. After an hour he became more quiet, and fell asleep. After an hour's sleep he seemed somewhat better. The pupils were still widely dilated, but the hallucinations were not so vivid.

On telling a professional friend of the curious actions of the patient, he remarked that the symptoms were similar to those which he once saw in the cases of two children who had eaten stramonium; and it immediately occurred to me that such was the case with my patient. He vomited several times during the night, and would wake up and go through his performances; but not so badly as during the evening.

On the morning of February 23 he was much better. The crazy actions had disappeared, but the pupils were still considerably dilated, cheeks flushed, and he was very thirsty. He ate a good breakfast, and before night was apparently as well as ever. In the matters vomited during the night were a number of of stramonium seed. I found, on inquiry, that his father had kept a patch of stramonium plants in the corner of his yard, which he used in making ointment for horses. The boy had cut one of the dry stalks, which was hanging with pods full of seed, and had eaten a quantity of the seed. After finding the cause of the child's sickness, the mother remembered his bringing the stalk on the porch, and saying that he had cut a tree.

The case is of still further interest as showing that stramonium poisoning is quite possible in winter, if there be any of the dead plants about with pods full of seed.

Pelvic Tumor Complicating Pregnancy.

Dr. John W. Taylor thus writes in the *Brit. Med. Jour.:*

The signs and symptoms attendant on the case of pelvic tumor described by Dr. Horrocks in the *Journal* of March 6th, are so very similar to those which we have often found in Birmingham to be associated with distension of the Fallopian tube, that I may, perhaps, be pardoned for suggesting the possibility of the presence of this condition in the case which he has published.

If acutely distended, the tube may be of almost solid hardness; although, when examination is repeated, there will probably be found a time or times when there is some elasticity or semi-fluctuation, indicating the probable presence of fluid. The tumor is generally intimately adherent to the back of the uterus, and can be traced from its posterior surface towards one or both sides, according as one or both tubes may be involved. It is decidedly tender to touch, and feels, on hasty examination, very like a retroflexed uterus. It is more likely to be mistaken either for this or for a myomatous outgrowth (subperitoneal fibroid) than for any other condition. Because it is adherent to the uterus, it moves rather rigidly with that viscus, and does not disappear on the use of the uterine sound, as a simple non-adherent flexion of the uterus may do. It is generally accompanied by pain, increased before and during menstruation; although, for some reason or other, it is not always the side affected that is the chief seat of pain. Sexual intercourse is usually painful; but all symptoms may be in abeyance when the condition is one of hydrosalpinx, and is chronic and stationary.

When confined to one side, it forms no bar to the occurrence of pregnancy. I have had until recently a case under my care, in which the signs of a distended tube have existed for nearly two years. The symptoms have been but slight, and consequently no operation has been performed. The patient is now about six months pregnant; and the tube, although somewhat larger in size than before the pregnancy, has not at present occasioned any serious inconvenience or difficulty. It is a question, however, which only increased experience can determine, whether this condition, when existing during pregnancy and labor, does not expose the patient to rather serious risk.

Hemorrhage is not a very common symptom of tubal occlusion and distension, but, when present, is apt to be severe, and, when accompanied by signs so nearly resembling nodular myoma of the uterus, may be speci-

ally misleading. I operated on a case presenting these features on December 10th of last year. Excessive menstruation had existed for four years, and latterly the patient had been "scarcely ever free" from hemorrhage. If absent for a few days, it was brought on again by the slightest exertion, and invariably by sexual intercourse. On two occasions, it had been so severe that the surgeon attending her had considered it necessary to plug the vagina. On examination, a resilient rather egg-shaped tumor was found high up behind and to the right of the uterus, feeling as if part of the uterus itself.

On operation, both tubes were found to be acutely distended and adherent behind the fundus of the uterus. The ovaries were cystic. The appendages on each side were carefully separated from their adhesions and removed, and are now in the museum of the Queen's College.

Since the operation, the hemorrhage has been much less, but menstruation has not as yet entirely ceased.

While fully recognizing that conclusions drawn from the description of a case are not, *prima facie*, likely to be so reliable as those from personal observation, my chief purpose will be attained if I succeed in drawing attention to the fact that chronic hydrosalpinx, both by signs and by symptoms, may occasionally closely simulate nodular myoma of the uterus, and need differential diagnosis from that affection.

The Cocci of Croupous and Hypostatic Pneumonia.

Dr. Lebashoff publishes in the *Russian Weekly Clinical Gazette* an account of some observations made with a view to determine the frequency with which microbes are present in cases of croupous and hypostatic pneumonia. He examined sections, the liquid contained in the lungs, the contents of the smaller bronchi, and also the fluid of the cerebral ventricles, and in some cases the blood from the heart and large venous trunks. The ordinary methods of staining not being very satisfactory, the author undertook a series of observations for the purpose of improving upon them, and found that the best method of staining lung sections was to immerse them for from two to five minutes in an aniline solution of gentian violet, and afterwards for from four to fifteen minutes in an aniline or watery solution of eosin, then to wash them and dry them with alcohol, and finally to treat them with clove or cedar oil. By this method of staining the micro-organisms could be seen to be distributed in a very irregular way, usually in groups. The cocci found in the centre of a lobulus always preserved their ordinary form, and were strongly stained; while single cocci towards the circumference were often hardly to be distinguished, being but slightly stained. While some of the cocci presented a distinct envelope, others apparently of the same variety were seen close to them without any envelope at all. The size of the pneumococci was not constant, this being perhaps due to the manipulations the section had undergone in preparing them for examination. The cocci seen by the author entirely corresponded with those described by Friedlander. Altogether there were examined forty-eight cases, forty-one of croupous and seven of hypostatic pneumonia. In the latter class of cases it did not seem that any characteristic cocci were constantly present, while in the forty-one cases of croupous pneumonia Friedlander's cocci were found in the lung tissue in thirty-eight cases. In eleven of these the fluid of the cerebral ventricles was also examined, cocci being found in eight. In the earlier stages of the disease the number of cocci was small; this gradually increased, attaining its maximum when red hepatization was changing into grey. The blood was examined in twelve cases, but no pneumococci could be discovered. The observations were carried on by cultivations in jelly and inoculations of animals. For cultivations in jelly the liquid from the lungs, the blood, and the fluid of the cerebral ventricles were used. Two kinds of colonies were met with. One kind was obtained after inoculation not only of pneumonia, but of other diseases, and of putrescent blood. The second kind differed from these in being of a dull white without any admixture of gray, and in being distinctly raised above the surface of the jelly. This kind was only observed after inoculation from croupous pneumonia. From ten inoculations with pneumonic lung juice these colonies were obtained eight times; five inoculations with ventricular fluid were twice successful, and three inoculations with blood only once. Experiments with mice showed that when these animals were inoculated from colonies of the second kind they developed croupous pneumonia, and in one case out of three in which the greyish cocci were inoculated, croupous pneumonia also followed. The author remarks that further observations are necessary on this subject, since mice are very subject to croupous pneumonia, and it is possible that numbers of other micro-organisms may have the power of setting up the disease in them.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

IS BOAT RACING INJURIOUS?

On the whole, we would answer this question affirmatively. There can be no doubt that the excessive strain placed upon the heart as well as upon all other parts of the body, by the violent exertions always made to be victorious, must, in the majority of cases, result disastrously. The *London Lancet* evidently takes a different view, as is evidenced by the following quotation:

"The annual contest between Oxford and Cambridge for aquatic supremacy proved this year to be one of unusual severity, and two, if not three men in both crews, towards the end of the race, showed evident symptoms of distress. This fact has led to some sensational statements being made to the effect that some of the men will never get over the consequences of their exertions. We believe, however, that such statements have no real foundation, and, beyond the fact that the men were temporarily distressed, nothing like permanent mischief is likely to result. Some years ago, before the conditions of training were thoroughly understood, such rumors were frequent after each great boat race, and even very eminent medical authorities set their faces steadfastly against boat-racing as an exercise. But a close inquiry into the after-history of the crews of the Oxford and Cambridge boats has proved conclusively that the mortality among the heroes of the annual race is certainly not greater than among the average of university men generally. The names of Sir Balliol Brett, Bishops Wordsworth, Selwyn, and Macdougall, Dean Merivale, Hon. G. Denman, J. M. Croker, and F. M. Arnold, are well known as those of members of victorious crews more than forty years ago, who have survived up to quite a recent date—indeed, some are still living; and to these may be added names, less known to fame, who were still able to answer *Adsum* when the roll was called a few years since. Sir George Burrows, who is still living, has told us he took part in one of the earliest of the college races on the Cam, quite fifty years ago; whilst Lord Penrhyn, who has just died at the advanced age of eighty-six, was a member of a crew who, in 1824, performed the extraordinary feat of rowing, with five others, from Oxford to Westminster Bridge within sixteen hours, a distance of 118 miles, with many locks to pass through, in one of the heavy wherries and with oars of the period—a performance far more severe than rowing a four-mile race: for, with a heavy six-oared wherry, they had to keep up the pace continuously, except at the locks, for

sixteen hours, at eight miles an hour; whilst, with light outriggers, sliding seats, and improved oars, the pace of the racing eight is little over twelve miles an hour for twenty minutes. A reason in favor of boat-racing as an exercise is the fact that the progress from ordinary to severe exertion is made very gradually. The tyro who first commences to row has to learn first to manage his oar; as soon as his muscles get accustomed to the weight, he is taught to bring his whole muscular system into action to propel the boat; but this has to be done gradually, otherwise he will acquire awkward habits. As soon as he has learned to row, he begins to cultivate pace, but this has to be practiced cautiously, since if allowed to "blow" himself, he will soon row out of form; and it is only by degrees that the bursts are lengthened as the "wind" improves. Next, after considerable preparation, come the "trial" races, in which the men's physical and staying powers are closely watched; and then comes the final selection into the crack crew. The result is, that an unsound man is usually found out long before the severe trial comes; whilst, for sound constitutions, a course of systematic and careful training tends to improve the physical and vital powers, and fits men to undergo the strenuous exertions of a boat-race without injury."

Whenever we desire to prove any given point we can almost always find *exceptional* cases that *seem* to furnish this proof. But argument for a general principle based upon exceptional instances is fallacious argument, and we fear that the *Lancet* in its endeavor to uphold a sport that is very popular in England has erred on the side of leniency. Rowing (easy, lazy paddling) is no doubt very good exercise, but we fear that *racing* cannot be commended from a sanitarian's point of view.

CHOLERA AGAIN.

An English exchange says: "The reported recurrence of cholera in Brittany enforces the caution contained in our recent issue as to the danger this country may have to face during the rainy season, on account of cholera on neighboring coasts. For the moment no news is forthcoming as to the prevalence of the disease on the north coast of Spain, but there can be little doubt that cholera is prevalent in certain portions of Brittany, and especially in and about Treboul. Probably the disease is of a more or less sporadic character, and hence the denials as to the existence of Asiatic cholera; but whatever form the disease assumes, it is clear that it is an affection having very near affinities to the epidemic which prevailed in France in 1884 and 1885; and in view of the communications between the coast of Brittany and our own coasts by means of fishing-boats, etc., it is important that our port and riparian sanitary authorities should be on the alert."

We reproduce this paragraph, because we believe that a little "cholera scare" usually has a wholesome influence. While we fully appreciate the evil influence of *fear* when the disease is epidemic in a locality, yet, at the same time, we also know that an "*ante-epidemic*" scare is never to be regretted. We are quite sure that the citizens of Chicago do not regret the one hundred thousand dollars spent last year in putting their city in proper sanitary condition, money appropriated under the spur of a "cholera-scare," and we are also sure that the house-to-house visitation and the general "cleaning-up," has done no harm to our city. To be forewarned is to be forearmed. Because we did not have cholera last summer is not a valid argument that we will not have it next. The powder is laid; it requires but the spark of of sanitary neglect to set it ablaze, and the unguarded entry of but one vessel to devastate our country. "A word to the wise is sufficient."

PROFESSOR FORBES OF "THE JEFFERSON."

Could the late Emeritus-Professor, Joseph Pancoast, unite with the present Emeritus-Professor, William H. Pancoast, we doubt not that they would jointly congratulate the Jefferson Medical College in having so worthily filled the chair that has been graced by distinguished father and distinguished son for so many, many years. The Trustees of the Jefferson Medical College had a very delicate duty to perform, for among the candidates for the chair of anatomy were so many distinguished anatomists, all thoroughly capable of filling the chair, and some pre-eminently so, that it became a matter of no small difficulty to make the most fit selection.

The Trustees have decided. Dr. William S. Forbes sits in the "Chair of the Pancoasts," and we heartily and sincerely congratulate both College and Professor on this fact.

STATE SANITARY CONVENTION.

We desire to call special attention to the circular from the State Board of Health, in reference to the Sanitary Convention, which

we publish on another page. This is a splendid programme, the nature of the work of the convention is of vital importance, and we sincerely trust that the place of meeting will be filled to overflowing throughout the sessions of the Convention.

Notes and Comments.

Three Peculiar Cases of Pneumothorax.

Dr. Samuel West read a paper on this subject before the Clinical Society of London, of which the following is an abstract:

Case 1. Three months ago, the patient had sudden dyspnœa while in bed. There was no cough before, but cough and expectoration came afterwards. He was at work the day before the attack. Ten days before admission the dyspnœa gradually grew worse, with pain in the side. Pneumothorax of the right side, with effusion, was found. Tapped; 41 ounces sero-purulent fluid withdrawn. Pressure was high. Tapped again fourteen days later; 22 ounces removed. Complete recovery. The patient was living and well, and in active work, three years afterwards.

Case 2. Phthisis of nine months' duration. Pneumothorax of the right side occurred in hospital. Death, two days later, was chiefly due to choking, by contents of a large cavity forced by compression of the lung into the bronchi.

Case 3. Sudden attack three weeks before admission. Cough only for two months; that is, five weeks before the attack. Admitted for dyspnœa and hæmoptysis. Pneumothorax of the right side, with effusion, was found. Paracentesis, and 28 ounces of sero-purulent fluid withdrawn. Paracentesis, 36 ounces of pus, three weeks later. Spontaneous discharge of pus, by the puncture, occurred a few days later. Free incision. Two days after, hemorrhage from the pleura by the incision, and hæmoptysis for a few days. Death from exhaustion about twelve days later, without further hæmoptysis.

Remarks.—Case 1. (*a*) The cause probably phthisis. (*b*) Pressure high. (*c*) Composition of the gas. (*d*) The nature of the effusion. (*e*) The dilatation of veins. (*f*) Prognosis in pneumothorax.

Case 2. The chief cause of the dyspnœa in the case, namely, the discharge of the contents of cavities into the bronchi, was not often described.

Case 3. Aneurism of the pulmonary artery and pneumothorax were rarely associated. They were, as it were, opposed processes. The proposed treatment of profuse hæmoptysis by the artificial production of pneumothorax was criticised.

Decoction of Lemons in Intermittent Fever.

Having reviewed the literature of the subject (Maglieri, Stephens, Toropoff, Tommasi-Crudeli, Dominico Azzillo, Norman Forbes, Lauchlan Aitken, Putokhin), Dr. Nikolai N. Maslennikoff proceeds (*Kavkazsky Meditz. Sbornik*, vol. 39, Fasc. ii., 1885, p. 29) to describe his own observations on twenty cases of intermittent fever, treated by decoction of lemons in the Military Hospital in Temïr-Khan Shura, Dagestan region. Seven of the patients were affected by the fever for the first time, three for a second; those remaining had passed previously through several malarial attacks. In thirteen of twenty cases a quotidian, and in seven a tertian, variety was present. In sixteen cases the spleen was found to be enlarged and painful (in fourteen, both during the paroxysms and the intervals). The decoction was prepared after Maglieri's method, that is, every evening a whole fresh lemon was cut into very thin slices, put into eighteen ounces of distilled water in an earthen pot, and boiled (for two hours) until six ounces of decoction remained. On the next morning the liquid was forcibly strained through a piece of gauze, and then given to the patient to take immediately at several gulps. The decoction was used in that way for ten or fourteen successive days. In none of the patients did any gastric disturbances occur. The results obtained by Dr. Maslennikoff were not so successful as those by Dr. Putokhin. In only six cases, four of which were of quotidian fever and two of tertian, a cessation of paroxysms ensued. In two of the remaining patients, the paroxysms became less severe; and in three the type of fever underwent a change. In none did any alterations in size of the spleen take place. All cases where decoction of lemons had failed were subsequently, mostly very rapidly, cured by quinine. The general conclusion reached by the author is that, as far as severe Caucasian fevers are concerned, decoction of lemons has, except its agreeable taste and harmlessness, no advantages whatever over other substitutes for quinine.

Intolerance of Quinine and Morphine.

The free, popular use of quinine is always to be deprecated by physicians. It is a powerful drug, potent for evil, and must be only *intelligently* used. To point this caution we

note the two cases that Dr. F. A. Floyer reports in the *Brit. Med. Jour.:*

"Case 1. I was called to see a patient at an hotel, and found a gentleman, about 40 years of age, well built, recovering from a very severe attack of dyspnœa, which, apparently, had threatened to become fatal. The attack was sudden, and was accompanied by well marked urticaria, which appeared, in patches about the size of half a crown, all over his body. I ascertained that the cause of this disturbance was a dose of 'neuralgic drops,' which, on inquiry, was found to contain about 2½ grains of quinine. He had never been able to take quinine, and had before been attacked somewhat similarly on attempting to do so. Surely this has some bearing on the question of urticaria causing asthma.

"Case 2. Into the arm of a well-developed girl, aged 22, I subcutaneously injected one-twelfth of a grain of morphine. To my horror, she immediately turned deadly pale, threw back her head, and in a few seconds respiration ceased, and she was pulseless. Smelling salts was applied, although for the minute there was no perceptible respiration. She was to all appearance dead, but shortly began to recover. As soon as she could swallow, brandy was administered. Presently her eyes turned up, all color left her face, and she became violently convulsed. She recovered again, and, beyond feeling severe pain at the place of puncture, and the pain for the relief of which I gave the injection, she was quite herself. Shortly she began to experience the usual effects of the morphine, of which I only gave a small dose, as it was her first experience of the drug. I considered the symptoms to be the result of shock, due to the perforation of an oversensitive skin; especially as I found, on inquiry, that she had previously fainted on being vaccinated."

Catgut Suture of Patella.

At a recent meeting of the New York Surgical Society, Dr. A. D. Stimson exhibited a patella which, having had occasion to divide, he had subsequently united by catgut suture, but whether one or more he was unable to say. Union ensued without suppuration. About four months later, however, it was found necessary to excise the same knee-joint, and this afforded an opportunity of examining the patella, which also was removed. The line at which the bone was originally divided was practically invisible, and the specimen clearly demonstrated the capacity of catgut to retain the fragments of a divided patella in such apposition that firm bony union may result. In this case, however, the circumstances were immediately favorable to union; the fracture was clean and new, and was quickly united, whereas in ordinary examples of the injury encountered by surgeons neither of these conditions is likely to exist. In Dr. Stimson's case it is not unlikely that any method adopted for keeping the fragments closely applied might have been followed with precisely similar successful union, the wound being really united by first intention, and organization proceeding to the extent of osteogenesis. The author of the account expresses much regret at the omission he was guilty of in neglecting to make special note of the number of catgut sutures employed—whether one or more. But it really would seem that this is of little importance, for the same general result as he obtained would be gained whenever a fractured patella is forthwith placed under the conditions mentioned, whether by suture or otherwise.

Goitre.

This subject is discussed, as the writer saw it in the Himalayas, in the March number of the Dublin *Journal of Medical Science.* Beginning with a glance at its geographical distribution, which includes not alone large portions of these mountains, but also Tibit and Bhootan, and such remote regions as Yarkand and Kashgar—in other words, all the table-lands of Central Asia—Dr. Curran describes the treatment that is resorted to for it on the spot, and shows that this consists mainly, if not exclusively, in a very free use of the moxa. Illustrations in point are given, and our author asserts that the people are firm believers in its efficacy. He then discusses the etiology of the complaint, and setting aside as improbable or unproven the ice-water hypothesis as well as the weight-on-head carrying theory, as he calls it, he ascribes it to the secluded lives and impoverished surroundings of these poor people. He ascribes it, in a word, to heredity, breeding in-and-in, and especially to the "poor monotonous vegetable dietary" to which their "poverty rather than their will consents." Whatever we may think of this hypothesis, it has the undoubted merit of meeting all the requirements of the case, as these are seen or can be studied on the spot, and the paper will otherwise raise the repute of its author. We strongly commend the perusal of it to our readers, as well as to all who take an interest in the pathology or diffusion of this obscure malady.

The Tests for Cocaine.

In *Pharmaceutische Centralhalle* of March 26, H. Beckurts criticises the tests for cocaine given by the German Pharmacopœia Commission. These tests are—(1) That the alkaloid and its salts should leave no residue on ignition, and (2) should not give any color with sulphuric acid. While the latter test is sufficient to detect substances other than cocaine extracted from the leaves, it does not afford any color with decomposition products of cocaine which may be formed through the influence of acids and alkalies. Owing to various conflicting statements which have recently been made, the author was led to study the influence of the proportions of alkaloid and acid upon the non-production or production of color, and he finds that one of cocaine hydrochlorate gives a colorless solution with fifty of sulphuric acid, but with three to four times that quantity of acid a yellow to red solution is formed. He therefore concludes that if the test is to be of any value, the proportions must be stated; but he is inclined to abolish the test altogether, because some samples which he knew to be grossly impure responded favorably to it. For it Giesel's permanganate test might, with certain modifications, be substituted. This test depends upon the fact that a weak aqueous solution of potassium permanganate gives a copious violet-red precipitate with a soluble salt of cocaine. Beckurts finds that on the addition of the first five drops of permanganate solution the permanganate salts suffer reduction with separation of manganese oxide, and it is only when large excess of the solution is added that the violet precipitate separates. If there be any decomposition products present, these are detected by the bitter-almond odor on boiling.

Myxœdema with Flexures.

Before the Medical Society of London, Dr. Ord showed a woman who exhibited the typical features of myxœdema, and, in addition, flexure of the hands, etc., was present. These flexures were not very obstinate, and were probably functional in character. No affection of the sensory functions.

Dr. Stephen Mackenzie asked whether the flexures relaxed during sleep.

Dr. Beevor called attention to a certain tremulousness in the patient, and mentioned that Dr. Horsely had found similar tremors in animals whose thyroid gland he had removed.

Dr. Heron alluded to the lapse of time which occurred between a question and the answer, and said that patients had assured him that they understood the questions quickly enough, but were conscious of an inability to reply promptly.

Dr. Drewitt asked Dr. Ord whether there was any heredity in this case.

Dr. Ord, in reply, said that the spasm relaxed during sleep. The tremors noticed by Dr. Beevor were probably due merely to excitement. He had known at least three cases which appeared to be hereditary.

Spinal Sclerosis and Osteo-Arthritis.

Before the Medical Society of London, Dr. Ord also exhibited a case, apparently of disseminated spinal sclerosis. All the joints of both hands were deformed, being of the nature of osteo-arthritis. Considerable thickening of the joints, with ankylosis, existed; there was much muscular atrophy of the hands, and also a glossy skin. The tremors and rigidity of limbs had in great degree diminished. The association of several dystrophies with the spinal symptoms was very noteworthy. The osteo-arthritis and atrophy of muscle and skin had been present about three years. Probably the loss of power, tremors, rigidity, and trophic changes were all due to one and the same spinal affection. Dr. Beevor asked whether it might not be a case of paralysis agitans. Dr. Ord could not accept this view.

Complete Rupture of Kidney.

To the Liverpool Medical Institution, Dr. Macfie Campbell showed a complete rupture of the kidney. The patient was a boy aged nine years, who was run over by a fire-escape. On admission to the Northern Hospital he was much collapsed, and complained of pain over the navel and pubes. A small quantity of bloody urine was drawn off. Rupture of bladder was diagnosed, and the viscus was opened supra-pubically and a drainage-tube inserted. No rupture was found, and further exploration was impossible, on account of the lad's condition of collapse. He died in twenty-four hours.

Post-mortem.—The pelvis and abdomen were full of blood, and the left kidney was found completely divided across, the capsule even being ruptured.

On the Transplantation of Teeth.

Experiments have recently been made by Dr. Younger, of San Francisco, on the subject of the transplantation of teeth, with a view to their growth in the new position. It

would appear that, if proper precautions be taken to secure perfect apposition and cleanliness, the operation is often attended with success, and possesses many advantages over the use of false teeth. The inflammation of the gums, however, is somewhat persistent, and constitutes a drawback, from the inconvenience which results therefrom. Recourse to this method is more particularly indicated when the teeth to be replaced are front teeth, and essential both for appearance sake, and for perfect articulation.

Inversion of the Temperature Curve.

Dr. Coriveaud draws attention in the *Journal de Médecine de Bordeaux* to some cases of pneumonia in children in which the ordinary temperature curve was inverted. A similar observation has, it seems, been made by Damaschino, in a thesis published in 1867, as he says: "In broncho-pneumonia the evening exacerbation is not always constant. In some cases the fever is as high in the morning as in the evening; in others the morning readings are even higher than those taken in the evening." Hirtz, too, in his article "Chaleur," in Jaccoud's Dictionary, mentions that in acute phthisis the morning temperature is occasionally higher than the evening.

Correspondence.

A Few Thoughts on the Clinical Thermometer.

Eds. Med. and Surg. Reporter:

One of the results noticeable from the now general use of the fever thermometer that is extremely unpleasant to the general practitioner, especially when we have an endemic (slight or otherwise) of some of the forms of continued fever, is this: that the friends and even the patient, while they know little or nothing as to the variations of temperature, not even the normal temperature of the human body, after the thermometer has been used once or twice, thereafter demand to know the daily rise and fall, commenting upon each, and often ready to go off in a tangent if there be a perceptible rise, which, perhaps, the physician understands as the natural sequence of the disease, indicating simply the natural progress of the disease, but which cannot be made to correspond to the friend's idea, and a consultation of physicians is at once ordered, or, perhaps, the physician, fully able to take the continued charge of the case and conduct it through to a successful termination, is forthwith discharged and another called.

But this is not all; it occurs to us that the patient himself has learned to ask to see the record of his temperature—yes, demand it; and if refused, the effect is likewise bad and depressing, because he imagines he is refused because he is worse, etc., etc. One is driven to desperation frequently as to how to escape this unpleasant dilemma, and forced to resort to all sorts of expedients to detract the attention from the thermometer, while in some cases he skillfully manages to *shake* the index to a point that would please his patient. But all this is unpleasant, and one does not enjoy the deceit that one must resort to, or allow his patient to realize each day that he is gradually growing worse---if it be so. But what shall we do? I have known two or three families who have had some long-continued cases of fever in their homes, to secure a thermometer and retain it for their own satisfaction, and the profession will understand how much satisfaction they received, watching the sudden rising and falling of the temperature of a loved member of the family. But where is this going to end? In all families having their "thermometer," I fear, just as they have the regulation syringe. I hope not, for their own peace of mind and for the good of the profession—and especially the young doctor. His chances of retaining a case right through, I am afraid, would be slim, as how many times an elevation in temperature, perfectly under the control of the physician, would be the signal announcing his discharge. This reminds me of an incident occuring in my office yesterday, which illustrates how the most unlearned have already learned to depend upon the little glass instrument.

Mrs. —— with her daughter, after an opinion by myself that the daughter's trouble was purely "bronchial." "Sure," says the mother, "doctor, you didn't try the little glass thing that goes in the mouth? Sure, Mrs. Mc—— towld me that you would put a little glass thing in her mouth, and that would tell just where the disease was, entirely." I used the "little glass thing," and thereby suited the interested mother at once; and I dare say, that while my opinion was taken as absolute after using the thermometer, it would not have been taken had I not used it; but a doctor would have been found who used the "glass thing." Again, where will it end? Shall we practice regular deceit, or shall we bulletin at each visit the exact condition to friends and patient?

C. G. Hollister, M. D.

Union City, Pa.

Rhus Poisoning.

EDS. MED. AND SURG. REPORTER:—

In regard to the communication of C. E. D., of Bedford, N. Y., page 413, I may say that swamp sumach is *rhus venenata*, a shrub six to twelve or more feet high, compound leaves, seven to thirteen leaflets, nearly always found growing in wet or swampy places, quite poisonous, as I have occasion to remember. Rhus toxicodendron grows upon dry land, erect, decumbent, oftener climbing by rootlets upon rocks, trees, etc., leaflets in threes, poisonous to some people, but to a less degree than the former. In California we have rhus diversiloba, quite abundant on dry ground and along creeks, seldom seen climbing, although it will climb by rootlets; leaflets in threes, and seems almost if not quite as poisonous as rhus venenata. All through spring and summer (occasionally in winter), I see numerous cases of poisoning from this rhus (commonly known as poison oak), more or less severe according to the extent of surface affected. The best remedy I have found is the following:

℞.	Borax, pulv.,	ʒij.
	Acid, carbolic,	ʒj.
	Morphia, sulph.,	grs. x.
	Pulv. acacia,	ʒiv.
	Water, q. s. ad.,	℥viij.

M.—Agitate till solution is formed. Use with camel-hair brush.

The carbolic acid and borax doubtless help to kill the poison, while with a few brushings the skin becomes coated with the gum, and the irritation and pruritus are allayed.

I do not believe that the poison "lives in the system," although it is the belief of many of the common people, for which they take sarsaparilla and iodide of potash.

San Mateo, Cal., Apr. 9, 1886. L. D. M.

Tying the Cord.

EDS. MED. AND SURG. REPORTER:

Several months since an article was published in the REPORTER on "Tying the Cord;" since then, scarcely a number has been published that has not had an article on the subject. I do not wish to give an opinion on when, where, how, or why, to tie the cord, but simply to give a hint which I have learned from experience.

A few weeks ago I was called to confine a lady, and, as frequently happens, I arrived there some time after the child was born. The nurse had it washed and dressed, and, so far as the child was concerned, all was apparently well. I delivered the placenta and gave the woman the necessary attention; and a few moments thereafter was about leaving when my attention was called to the child, whose clothing was saturated with blood. Surmising its origin, I had the clothing removed and found simply a heavy thread wound around the cord several times, as we frequently find fingers done up.

Moral.—In such cases, always examine carefully the nurse's work.

NEWS AND MISCELLANY.

State Sanitary Convention

UNDER THE AUSPICES OF THE STATE BOARD OF HEALTH,

In M'Caull's Opera House, Broad street below Locust, Philadelphia, Wednesday, Thursday, and Friday, May 12, 13, and 14, 1886.

The following circular, which we print as received, explains itself:

Commonwealth of Pennsylvania.

The object of this convention will be to afford an opportunity for an expression of opinion on matters relating to the public health and the discussion of methods looking towards an advancement in the sanitary condition of the commonwealth, the prevention of sickness and avoidable death, and the improvement of the conditions of living.

ORGANIZATION OF THE CONVENTION.

President.—Wm. Pepper, M. D., LL. D., Provost of the University of Pennsylvania.

Vice-Presidents—Hon. William B. Smith, Mayor of Philadelphia; Hon. James Pollock, Hon. J. F. Hartranft, Hon. Henry M. Hoyt, ex-Governors of Pennsylvania; Hon. Richard Vaux, Hon. Samuel G. King, ex-Mayors of Philadelphia; Hon. A. F. Mizener, Mayor of Erie, Pa.; Hon. Lewis C. Cassidy, Attorney-General of Pennsylvania; Hon. Wm. S. Stenger, Secretary of the Commonwealth of Pennsylvania; Hon. J. Simpson Africa, Secretary of Internal Affairs of Pennsylvania; Hon. Jerome B. Niles, Auditor-General of Pennsylvania; Hon. James I. Mitchell, Judge Court Common Pleas; Hon. James Gay Gordon, Judge Court Common Pleas; Hon. James H. Campbell, ex-Postmaster-General United States; Hon. Robert Adams, Jr., State Senator; Hon. A. K. McClure, editor *Times;* Right Rev. Willliam Bacon Stevens, D. D.; Right Rev. Edmund de Schweinitz,

D. D., Bethlehem, Pa. Right Rev. Cortlandt Whitehead, D. D., Pittsburgh, Pa.; General Presley N. Guthrie, Adjutant General of Pennsylvania; General J. P. S. Gobin, Lebanon, Pa.; General George R. Snowden, Philadelphia, Pa.; Colonel Richard S. Edwards, Quartermaster-General of Pennsylvania; Mr. Charles Emory Smith, editor *Press;* Mr. Robert S. Davis, proprietor *Call;* Mr. Louis N. Megarge, editor *News;* Mr. William M. Singerly, proprietor *Record;* Dr. Daniel G. Brinton, editor MEDICAL AND SURGICAL REPORTER; Mr. J. Clarke Davis, *Inquirer;* Mr. James R. Gates, President Select Council, Philadelphia; Mr. Charles Lawrence, President Common Council, Philadelphia; Mr. John Bardsley, Chairman Finance, Common Councils; Colonel William Ludlow; Mr. H. G. Sickel, President Board of Health of Philadelphia; Mr. A. A. Hirst, Secretary Board of Health of Philadelphia; Mr. John Wanamaker; Col. Robert P. Dechert, Controller of Philadelphia; Major Moses Veale, Health Officer of Philadelphia; Dr. Wm. M. Welch, Physician-in-charge Municipal Hospital, Philadelphia; Dr. Henry Leffmann, Port Physician; Dr. F. S. Wilson, Lazaretto Physician; Dr. Roberts Bartholow, Dean Jefferson Medical College; Dr. A. R. Thomas, Dean Hahnemann Medical College; Dr. P. D. Keyser, Dean Medico-Chirurgical College; Dr. Rachel L. Bodley, Dean Women's Medical College of Pennsylvania; Dr. R. J. Levis, President Philadelphia County Medical Society; Dr. William H. Pancoast, Emeritus Professor of Anatomy, Jefferson Medical College; Dr. D. Hayes Agnew, Professor of Surgery, University of Pennsylvania; Dr. William B. Atkinson, Secretary American Medical Association; Dr. P. H. Bailhache, U. S. M. H. S.; A. H. Fetterholf, Ph. D., President Girard College; Mr. Samuel C. Perkins, President Public Building Committee; Mr. Wm. B. Land, Secretary Public Building Committee; Mr. John Gay, President Commissioners of Fisheries; Mr. Samuel L. Smedley, Chief Engineer and Surveyor of Philadelphia; Mr. Wm. Dixey, Commissioner of Markets and City Property, Philadelphia; Mr. Cadwalader Biddle, Secretary Board of Public Charities; Mr. George A. Cotton, President Board of Port Wardens; Mr. Christopher Stuart Patterson, Secretary Eastern Penitentiary; Mr. Frederic Collins, President House of Refuge; Mr. A. M. Spangler; Mr, W. Heyward Drayton, President Directors City Trusts; Mr. Richard L. Ashhurst; Captain W. Stokes Boyd; Mrs. E. D. Gillespie.

Programme.

Owing to the large number of papers to be read, the committee earnestly request the participants to adhere closely to the apportionment of this programme. The audience are invited to take part in the discussions, which must be limited to *five minutes* for each participant.

WEDNESDAY, MAY 12.

Morning Session.

10 a.m. Prayer by the Rev. Matson Meier-Smith, D. D., Professor in the Philadelphia Divinity School. Introductory remarks by the President. Address of welcome by His Excellency, Robert E. Pattison, Governor of Pennsylvania.

11 a. m. "Prevention of Communicable Diseases." By Morton Prince, M. D., of Boston, Mass.

11:30 a. m. "An Epidemic of Diphtheria Traced to Its Source." By Benjamin Lee, A. M., M. D., Secretary State Board of Health of Pennsylvania.

12 m. "Tests for Impurities in Water." By H. F. Formad, M. D., of Philadelphia, Lecturer on Experimental Pathology, University of Pennsylvania.

12:30 p. m. "Necessity of Physical Education." By Carl H. Horsh, M. D., of Dover, N. H., Member State Board of Health of New Hampshire.

Afternoon Session.

2 p. m. "Importation of Foreign Rags into American Ports." By F. S. Wilson, M. D., Lazaretto Physician.

2:30 p. m. "Heating and Ventilation of Public School Buildings," as illustrated by the system introduced into the new High School building at Chester. By D. W. Jefferis, M. D., of Chester, Pa.

3 p. m. "Narcotic Appetites." By J. Lowry Sibbett, M. D., of Carlisle, Pa.

3:30 p. m. "Economic Sanitation." By Albert L. Gihon, M. D., Medical Director, U. S. N.

4 p. m. "Our Drugs and Medicines." By L. Wolff, M. D., President Pharmaceutical Examining Board of Philadelphia.

4:30 p. m. "Physic, Tippling, and Medicine Bibbing," a warning against intemperance in the use of drugs. By Frank Woodbury, M. D., Professor of Materia Medica and Therapeutics in the Medico-Chirurgical College of Philadelphia.

5 p. m. "Healthy Dwellings." By V. C. Vaughan, M. D., of Ann Arbor, Michigan, Member of Michigan State Board of Health,

Discussion by Mr. George N. Bell, C. E..

of Newport, R. I.; Mr. William B. Land, Secretary Public Building Commission, Philadelphia; A. R. Thomas, M. D., Dean Hahnemann Medical College.

Evening Session.

Annual address before the Board.

8 p. m. "The Obligation of States and Citizens to Preserve the Health of the People." By Hon. Erastus Brooks, of West Brighton, N. Y., Member New York State Board of Health.

THURSDAY, MAY 13.

Morning Session.

10 a. m. "Drainage and Sewerage of Cities and Towns." By Colonel George E. Waring, Jr., of Newport, R. I.

Discussion by Hugh Hamilton, M. D., of Harrisburg, Pa.; John G. Richardson, M. D., Professor of Hygiene, University of Pennsylvania.

11 a. m. "The Relations which the Topography of Harrisburg, Pa., Bears to its Drainage and Sewerage." Illustrated by maps and charts. By Hugh Hamilton, M. D., of Harrisburg, Pa.

11:45 a, m. "The Majesty of Law in Sanitation." By Rev. J. Andrew Harris, D. D., of Chestnut Hill, Pa.

12:15 p. m. "The Prevention of the Spread of Scarlet Fever." By W. W. Vinnedge, M. D., of Lafayette, Indiana.

12:30 p. m. "Means of Elevating the Standard of Supplies." By Mr. H. Wharton Amerling, of Philadelphia.

12:45 p. m. "The Adulteration of Candy." By E. A. Heintz, Editor *Confectioner's Journal*, Philadelphia.

Afternoon Session.

2 p. m. "Heredity and Other Peculiarities Affecting Health and Longevity." By C. W. Chancellor, M. D., of Baltimore, Md., Secretary State Board of Health of Maryland.

Discussion by A. J. B. Jenner, A. M., M. D., of Detroit, Michigan; J. G. Richardson, M. D., Professor of Hygiene, University of Pennsylvania.

2:45 p. m. "The Duties of Sanitary Authorities in Reference to the General Use of Alcohol." By Prof. Henry Leffmann, M. D., of Philadelphia.

3 p. m. "Hygiene of Old Age." By Prof. H. C. Wood, M. D., of Philadelphia.

Discussion by Laurence Turnbull, M. D., of Philadelphia.

3:30 p. m. "The Influence of Overwork in the Production of Nervous Diseases and Insanity." By Prof. C. K. Mills, M. D., of Philadelphia.

4 p. m. "Defective Vision in School Children." By Prof. P. D. Keyser, M. D., of Philadelphia.

Discussion by A. J. B. Jenner, A. M., M. D., of Detroit, Michigan.

4:30 p. m. "Municipal Sanitation." By H. B. Horlbeck, M. D., of South Carolina, Health Officer of Charleston.

Discussion by Morton Prince, M. D., of Boston, Mass.

5 p. m. "Vaccination." By Dr. Wm. M. Welch, Physician-in-charge Municipal Hospital, Philadelphia.

Discussion by A. J. B. Jenner, A. M., M. D., of Detroit, Michigan.

Evening Session.

8 p. m. "Water Supplies of Towns and Cities." By Charles Smart, M. D., Major and Surgeon, U. S. A.

FRIDAY, MAY 14.

Morning Session.

10 a. m. "Artificial Feeding of Infants." By John M. Keating, M. D., of Philadelphia.

Discussion by Prof. Albert R. Leeds, M. D., of Stevens' Institute of Technology, Hoboken, N. J.; A. J. B. Jenner, A. M., M. D., of Detroit, Michigan.

10:45 a. m. "The Water Supply of Philadelphia." By J. Cheston Morris, M. D., of Philadelphia.

Discussion by Prof. Albert R. Leeds, M. D.; Charles W. Dulles, M. D., of Philadelphia.

11:45 a. m. "Mistakes in School Architecture." By J. H. McClelland, M. D., of Pittsburgh, Member of State Board of Health of Pennsylvania.

Discussion by Prof. P. D. Keyser, M. D., of Philadelphia.

12:30 p. m. "Disposal of Human Excreta by Fire." By W. S. Ross, M. D., of Madisonville, Ky.

Afternoon Session.

2 p. m. "Influence of Diet on Health." By A. K. Hills, M. D., of New York.

2:15 p. m. "The Financial Aspect of Sanitation." By Alfred Ludlow Carroll, M. D., West New Brighton, New York.

2:30 p. m. "Social Sanitation among the Japanese." By D. R. Simmons, M. D., of Yokohama, Japan.

3 p. m. "The Sanitary Significance of Sporadic Typhoid Fever." By Pemberton Dudley, M. D., of Philadelphia, member State Board of Health of Pennsylvania.

3:30 p. m. "The Causation of Pneumonia." By Henry B. Baker, M. D., of

Lansing, Michigan, Secretary Michigan State Board of Health.

4 p. m. "Care of Animals in the Propagation of Vaccine." By Prof. W. L. Zuill, M. D., Professor of Comparative Anatomy, Veterinary Department, University of Pennsylvania.

The balance of this day's session will b devoted to voluntary remarks.

Among the many distinguished gentlemen who have promised to be present and take part in the discussions, besides those already announced in the programme, we note the following:

Charles Mitchell, M. D., Health Officer of Nashville, Tennessee; John B. Hamilton, M. D., Surgeon General United States Marine Hospital Service; Hon. John F. Hartranft, Col. Wm. Ludlow, Adjutant-General P. N. Guthrie; W. C. Cook, M. D., County Health Officer, Nashville, Tennessee; Edward W. Germer, M. D., Erie, Pennsylvania, President State Board of Health of Pennsylvania; Mr. Samuel L. Smedley, Chief Engineer and Surveyor of Philadelphia; W. J. McClure, Health Officer, York, Pennsylvania; George Homan, M. D., Albert Merrill, M. D., Members Missouri State Board of Health; W. F. Hyer, M. D., Member Mississippi State Board of Health; Dr. David Engelman, Easton, Pennsylvania, Member Pennsylvania State Board of Health; G. H. Wilson, M. D., Member Connecticut State Board of Heaith.

The headquarters of the Convention will be at the St. George Hotel, where special rates have been made for those attending the Convention.

PEMBERTON DUDLEY, M. D.,
BENJAMIN LEE, M. D.,
JOSEPH F. EDWARDS, M. D.,
Committee of Arrangements.

JOSEPH F. EDWARDS, M. D.,

EDWARD W. GERMER, M. D.,
Pres. State Board of Health of Penna.

American Medical Association.

The American Medical Association has been in annual session during Tuesday, Wednesday, Thursday, and Friday of this week in St. Louis. At the session on Wednesday, the Secretary, Dr. Wm. B. Atkinson, of Philadelphia, announced that the committee on the President's address would consist of Drs. Murphy, of Minnesota, Gihon, United States Navy, and Garcelon, of Maine. The nominating committee selected by the state delegations was then announced, each state being entitled to one member. H. J. Sharp, of Liberty, acted for Pennsylvania. The committee at once went into executive session, and agreed upon Dr. E. H. Gregory, of St. Louis, for the office of president during the coming year.

The Rush Monument Committee, appointed at the last meeting of the Association, reported they had selected an enlarged committee of one member from each state and territory to secure contributions to the fund. The contributions, which are limited to $1 each, are to erect a monument to Dr. Benjamin Rush, a signer of the Declaration of Independence, founder of Dickinson Medical College, and the most prominent of the early American doctors. The Judicial Council decided to admit the illegal delegation of the Philadelphia County Medical Society, against which a protest had been made. Dr. Nicholas Senn, of Milwaukee, read a long paper on Abdominal Surgery, and was followed by Dr. C. Gordon, of Portland, Me., with a paper on the Diseases of Women. In the section of practice of medicine, of which Dr. J. T. Whittaker, of Cincinnati, is chairman, Dr. Wm. Pepper, of Philadelphia, presented an able paper on "Nitrate of Silver in Catarrhal Jaundice." In the section of experimental researches, Dr. Henry H. Smith, of Philadelphia, discussed the proper treatment of penetrating wounds of the abdomen.

Wednesday evening the delegates were tendered a reception at the great hall of the Merchants' Exchange. More than 1500 of St. Louis' best citizens appeared to do them honor. After the reception the ball took place, and proved to be the social event of the year. Thursday night receptions were given at the homes of society leaders in honor of the guests.

A full report will appear next Saturday.

Surgeons to the Pennsylvania Company.

The seventh semi-annual meeting of the Association of the Surgeons to the Pennsylvania Company will be held in the parlors of the Wiler House, Mansfield, Ohio, Tuesday, May 18, 1886, commencing at 8:30 a. m., standard time.

PROGRAMME.

Roll call.
Reading of minutes.
Reports of committees.
Unfinished business.
New business.

REGULAR PAPERS.

"Intestinal Obstruction," Surgeon J. J. Larkin, South Chicago, Ill.

"Diphtheritic Wounds," Surgeon John A. Chesney, Bucyrus, O.

"The Comparison of Cases as an Aid in Treatment," Surgeon M. L. Brooks, Jr., Cleveland, O.

"Conservatism in Railroad Surgery," Surgeon J. H. Davisson, Warsaw, Ind.

"A Case of Railroad Surgery," Surgeon J. G. Buchanan, Allegheny, Pa.

Volunteer papers.

Adjournment at 3 p. m., standard time.

OFFICERS FOR 1886.

President.—W. H. Harper, M. D., Lima, Ohio.

Vice-President.—R. P. Johnson, M. D., Canton, Ohio.

Secretary and Treasurer. — R. Harvey Reed, M. D., Mansfield, Ohio.

Executive Committee.—Dr. J. H. Davisson, Warsaw, Ind.; Dr. A. W. Ridenour, Masillon, Ohio; Dr. G. W. McGarven, Van Wert, Ohio.

The Fifty-fourth Annual Meeting of the British Medical Association.

We understand that the arrangements for the forthcoming annual meeting at Brighton are well forward. Owing to the lamented death of Dr. Austin Flint, it has become necessary to find another gentleman to read the Address in Medicine. The choice has fallen on Dr. Billings, of Washington, who has signified by telegraph his willingness to accept the office. The international character of the meeting will thus be still maintained. It is also hoped that Professor Charcot will be present, and will take part in the discussions. To turn to another side of the picture, we hear that Sir Thomas Brassey has placed his world-renowed yacht, the "Sunbeam," at the disposal of the Association for four days during the meeting. For sea-going members, a trip in the "Sunbeam" in August will be delightful, especially if its distinguished owner (who has expressed a wish to do all in his power to promote the success of the meeting) be able himself to be present. On Wednesday, August 11, Sir Julian Goldsmid has invited the Association to an afternoon garden-party at St. Ann's Well, the old chalybeate spring of Brighton. The excursions already arranged include visits to St. Leonard's, Hastings, Tunbridge Wells, Eastbourne, and Chichester; and to Arundel Castle, by invitation of his Grace the Duke of Norfolk. We shall give further particulars as time goes on. For the present, signs such as these show that the local executive is actively at work; and that not only they, but the profession and residents of the town of Brighton, intend to do their utmost to render this an agreeable as well as an important meeting. From all accounts, it bids fair to be both.

Adulteration of Food.

Mr. Edwin W. Martin delivered a lecture last Wednesday night in the lecture-room of the School of Mines at Columbia College, New York, on "Adulteration of Food." The lecture dealt with only the commonest frauds practiced with ordinary articles of consumption. Mr. Martin spoke first of the matter of water contamination, and next of adulteration of milk. In speaking of the lactometer and its value as a test, he disagreed with the adverse criticism that has recently been passed on the instrument. Within a certain range he considered it perfectly trustworthy. Among other experiments the lecturer manufactured milk from chemicals, fats, etc., as was done during the siege of Paris. Some time was given to the consideration of tinned goods and the dangers they contain. For much of the adulteration now practiced, the lecturer said, the public were to blame. In the case of peas, nine out of every ten of the consumers would reject the pure article as of "bad color;" hence the use of adulterants. The French are adepts at this coloring of vegetables, which has recently been prohibited. In turn, the adulteration of condiments, confectionery, tea, coffee, bread, flour, and other common necessities of life, was investigated. Mr. Martin said, in conclusion: "Many of them are frauds on the purse rather than the stomach, but the principle is bad enough to be utterly condemned."

—Dr. T. Gaillard Thomas has removed from 294 Fifth avenue, New York, to 600 Madison avenue, between Fifty-seventh and Fifty-eighth streets.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDED APRIL 24, 1886.

Long, W. H., surgeon. Granted leave of absence for seven days, April 24, 1886.

Banks, C. E., passed assistant surgeon. Granted leave of absence for ten days, April 20, 1886.

Armstrong, S. T., passed assistant surgeon. Granted leave of absence for five days, April 20, 1886.

Items.

—Ohio will soon have a State Board of Health.

—The death is announced of Dr. Joseph Nowak, Professor of Hygiene in the University of Prague.

—Dr. E. T. Wells has been appointed to the Chair of Materia Medica in the College of Physicians and Surgeons, of Chicago, Ills.

—M. Vulpian has been elected, after a sharp contest with M. Milne Edwards, as permanent secretary to the Physical Science section of the French Academy of Sciences.

—The *Dakota Medical Brief* is a new journal which will published at Mitchell, Dakota. It is to be issued monthly, and edited by F. Andros, A. M., M. D., and H. S. Sevey, M. D.

—Dr. Jendrássic has found in cases of cardiac dropsy that calomel causes well marked diuresis, which dissipates the dropsy and œdema. The effect, "a sort of diabetes insipidus," comes on in twenty-four hours by giving one and a half grains of the drug three to five times a day. Salivation and sore mouth are prevented by using a gargle of chlorate of potash from the first.

—The Ohio Sanitary Association has elected the following officers for the ensuing year:

President—Dr. S. H. Herrick, Cleveland.

Vice-Presidents—Professor E. T. Nelson, Ph. D., Delaware; Dr. W. H. Phillips, Kenton; Dr. C. T. Langdon, Westerville.

Secretary—Dr. R. Harvey Reed, Mansfield.

Treaeurer—Professor John Simpson, Ph. D., Mansfield.

OBITUARY NOTICES.

Reynell Coates, M. D.

Dr. Reynell Coates, a physician well known in this city in former years, died at his residence in Camden on Tuesday of last week, of pneumonia. He was eighty-four years of age. Dr. Coates had an eventful career and was successful as an author, politician, and scientist. He was born in this city in 1802, and his father was the Quaker philanthropist, Samuel Coates. He received his medical diploma at the University of Pennsylvania in 1823, and made a voyage to Bengal as surgeon of an Indiaman, after which he settled down to the practice of his profession on shore. He was a man of fine personal appearance and of great courage. It is related of him that in 1829 he had a wordy dispute with President Andrew Jackson. The debate became so warm that the President, fearing he might lose his temper, turned his back on the young man, but was wheeled suddenly about and received a stinging slap in the face. Dr. Coates frequently spoke of this incident in the latter years of his life, but became greatly incensed if any one criticised his action.

In 1836 Dr. Coates became attached to the scientific corps of the South Sea expedition, at that time considered a stupendous undertaking. The expedition was under the command of Commodore Jones, and Dr. Coates was placed at the head of the department of comparative anatomy. When the scheme broke up a new expedition was formed, but Dr. Coates became detached from the service.

He drafted the address of the Native American party in 1844, and wrote the widely-known poem, "The Gambler's Wife."

In 1845, after the death of his wife and only child, Dr. Coates moved to Camden, where he has lived ever since.

Hiester H. Muhlenberg, M. D.

Dr. Hiester H. Muhlenberg, of Reading, Pa., died May 5, at the age of 75 years. He studied medicine with Naval Surgeon Thomas Harris, and graduated from Dickinson College afterward. At the panic of 1837 he was called upon to take charge of the Farmers' Bank, was elected its cashier, and served in that capacity from that time to January last. Dr. Muhlenberg was a lineal descendant of Peter Muhlenberg, the patriot preacher of the Revolution. His mother was a daughter of Gov. Hiester, of Pennsylvania.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

RIDGE'S FOOD

FOR INFANTS AND INVALIDS.

Cereal foods are regarded by some with disfavor, as diets for infants, especially by those who maintain the dictum of chemistry in the matter as conclusive. It is urged that as they usually contain a certain amount of unconverted starch, this ingredient, owing to the absence from a baby's saliva of the solvent "*ptyalin,*" must cause indigestion and irritation in its passage through the stomach and intestines. Yet Bouchardat and Sandras have demonstrated that starch, even to animals in excess of what the saliva can act upon, has its edges eroded, dissolved, and transformed into sugar, when it meets the pancreatic fluid in the duodenum. The inference is that the conversion of starch is not wholly dependent on the secretions of the buccal cavity, and that the presence of a limited quantity in an infant's food is not necessarily a source of disorder. Moreover, in dietetic questions the verdict of chemistry can only be received *cum grano salis*; and the final appeal is to practical experience; what might, could, would, or should be, under supposed conditions, loses much of its practical value, when we have easy access to what is.

The preëminent popularity of Ridge's Food has caused it to be singled out for special criticism and attack, and unsparing denunciations have been hurled at it by and on behalf of unsuccessful rivals, whose professed zeal for the welfare and protection of the innocent public would be really touching, if it did not employ the language of disappointment and defeat. Our appeal to the public for its patronage has rested on the excellence of our product; and its full justification is found at this time in an experience of thirty years, during which the sales of Ridge's Food, throughout Great Britain and her Colonies, as well as in every State in the Union, have steadily and largely increased.

Ridge's Food is made from carefully selected winter wheat which, having been reduced to an almost uniform fineness, is thoroughly cooked by a steam baking process. The nitrogenous and phosphatic elements, in which wheat is so rich, are carefully preserved, and a large proportion of the starch is converted into dextrine, while the residue undergoes a further change when the food is prepared, as directed, in the nursery, producing an article of diet at once abundantly nutritious and easily digested. Samples of the preparation will be found alittle sweet and slightly alkaline.

It is claimed for Ridge's Food that it is acceptable to the most irritable stomach of infant or invalid, when used (as sometimes it must be) without milk; and that then it is alone sufficiently nutritive to sustain life.

It is also ammed that the objections urged against the use of cereal foods in no way or degree apply to our preparation; that the consequences predicted as following such a diet for infants never occur where Ridges Food is used. So contrary, indeed, is the prediction to the results of experience, that an eminent firm of druggists in Chicago, who for many years have sold largely of our preparation write: "Its soothing and satisfying properties are so marked, as often to cause customers to inquire *it does not contain some opiate?*"

We shall be pleased to forward a sample of **RIDGE'S FOOD** to any physician not yet acquainted with it, who may favor us with their address, satisfied that, with a fair trial, we shall secure his commendation.

LECTURES ON INSANITY.

DELIVERED AT THE UNIVERSITY OF PENNSYLVANIA.

BY CHARLES K. MILLS, M. D.,

Lecturer on Mental Diseases in the University of Pennsylvania; Consulting Physician to the Insane Department of the Philadelphia Hospital; Neurologist to the Philadelphia Hospital; and Professor of Diseases of the Mind and Nervous System in the Philadelphia Polyclinic.

Reported by William H. Morrison, M. D.

Lecture IX.

ORDERS OF COURT IN CASES OF INSANITY—PROVISIONS OF THE PENNSYLVANIA LUNACY LAW—THE EMMA BICKEL CASE—THE NUTT CASE—POWER OF THE COMMITTEE OF LUNACY—DANGERS OF PHYSICIANS—THE HAAS CASE—A PERSONAL EXPERIENCE.

Gentlemen: The insane can also be placed in asylums or hospitals for the insane by order of court. Usually such orders are given in criminal cases. All cases sent to State and other hospitals for the insane, however, by order of court, are not criminal in character. To illustrate, the State Hospital for the southeastern district of Pennsylvania, located at Norristown, Pa., receives many free patients from the counties included in this district. In these cases the papers are prepared and taken before a judge of any one of the courts, before whom the relatives or friends of the patient make affidavit or affirmation that they are unable to support the patient; and if thought necessary, other questions are considered by the court, and then an order is made. In this connection it might be well to consider at once the discharge of cases by order of court.

Section 29 of the lunacy law of Pennsylvania of 1883 reads as follows: "The provisions of this act, in respect of the admission or discharge of patients, shall not extend to insane criminals in custody. Such persons shall not be received except when delivered by a sheriff of the county, or his deputy, together with an order of the court of the county in which he was arrested or convicted, having jurisdiction of the offense, under seal of the court, and signed by a law judge, nor shall such criminals be discharged from a hospital or other place of detention for the insane, saving on a like order, and to the sheriff, or his deputy, producing such order; and while detained as an insane person, such criminal shall be so kept as to insure his detention until duly discharged. Whenever any person, detained in any gaol or prison is insane, or in such condition as to require treatment in a hospital for the insane, it shall be the duty of any law judge of the court, under whose order the person is detained, upon application, to direct an inquiry into the circumstances, either by a commission or otherwise, as he shall deem proper, with notice to the Committee on Lunacy, and if the judge shall be satisfied that the person confined requires treatment in a hospital, he shall thereupon direct the removal of the said person from the gaol or prison to a State hospital, which order shall be executed by the sheriff of the county, or his deputy, and the actual expense of such removal and the expenses of maintaining the person in the hospital, shall be paid by the county liable for the maintenance of the said

gaol or prison from which he

ovisions of this section are very
id do not require much elaboration
xplanation by me. Difficulty is more
ly to arise from the discharge rather than
ne admission of patients under this section. We have recently had in this city an interesting case of this kind. Section 30, relating to the discharge of patients committed by order of court, and which defines the duties of officers of the institutions in this connection, is as follows: "The trustees, managers, and physicians of any hospital in which a criminal is confined by order of any court, or in which a lunatic has been committed after an acquittal of crime, shall not discharge, release, or remove the prisoner or lunatic without the order of a court of competent jurisdiction; and in case such lunatic, whether a convict or acquitted, is not set at large, but is removed to any place of custody other than a hospital, the order for removal shall not be made without notice to the committee of lunacy, and time given them to investigate the case and be heard on the application."

Every now and then it happens that a person who has been acquitted of homicide or other serious offense on the plea of insanity, and has been sent to a hospital for the insane by order of court, in a comparatively short time makes application through counsel for discharge on the ground of recovery from their insanity. The Philadelphia case to which I have just alluded is the now notorious "Emma Bickel case."

Emma Bickel, it may be remembered, shot and killed a man named Mennow. Both of these individuals were well known in the part of the city in which the tragedy occurred. Emma Bickel, whose maiden name was Sperry, married Bickel when she was only sixteen years old. The couple separated and she began to keep company with Mennow. It was, by some, believed that they were married. Both parties claimed at different times that they were married, and again that they were not married.

Trial lasted for several days. Testimony as to insanity in the family of the accused was introduced. The only expert testimony in favor of insanity given was by Dr. Henry C. Dwight. The commonwealth brought forward the testimony of Drs. Butcher and Sharp of the County Prison against insanity. Strong pleas to the sympathy and passions of the jury were made by the defendants of the prisoner, Col. Isaac Shields and A. S. L. Shields, esq. After a short deliberation, the jury acquitted the prisoner on the ground of insanity, and she was soon sent to the Norristown Hospital for the Insane on the order of Judge Mitchell.

After remaining in this institution for several months, application was made through the counsel who had defended her on the trial, for her discharge. A writ of habeas corpus was taken out, and the case came before Judge Mitchell for decision. In support of the application for discharge, a letter was presented from Dr. Alice Bennett, the Superintendent of the Female Department of the Insane Hospital, who certified that "Emma Bickel was not of unsound mind, and that she has been fully restored to mental sanity, and no longer needs the remedial care of the hospital aforesaid or any other, and therefore I respectfully recommend the discharge of the said Emma Bickel from the custody of said hospital authorities."

Testimony as to the present sanity of the patient was also given by a friend. Dr. Rebecca S. Hunt, assistant physician of the female branch of the Insane Asylum at Norristown, also testified that Emma Bickel had completely recovered her reason, and that it was safe for her to be at large. Dr. Thomas G. Morton, a member of the Committee on Lunacy, testified that he had examined the woman at the hospital, and that she appeared to him to be sane. On cross-examination, however, he said that if he took the finding of the jury of the fact, he should say that it would be unsafe to liberate her. After argument by the District Attorney and Mr. Shields, the question went to the Judge for decision. Mr. Shields' argument was that the woman had not been sent to the asylum as a punishment, but merely that she might remain until she had recovered her reason; and having regained her reason, she had an absolute right under the act of 1874 to be discharged.

Mr. Graham replied that the act of 1874 was not the only one applicable. That act, he held, was not intended to repeal the act of 1869, and was not repugnant to it, and consequently they could stand together. The act of 1874 applied to cases committed under it, and was intended to remedy defects in the old laws of 1844 and 1860, and it simply enlarged the power of the court vested by the act of 1869. He held that the evidence clearly established in the words of the act of 1869 that it was not safe for the woman to be at large.

During the hearing of the writ of habeas corpus, a most important and interesting side-question came before the judge for de-

cision. It was shown by the evidence, and admitted by Dr. Bennett, that on four occasions Emma Bickel had been permitted to leave the hospital—twice accompanied by an officer of the institution, once by a friend, and once unattended. The physician was apparently under the impression that she had a right to grant parole to such a patient, and allow her to go out for her health or other purposes, properly attended, as she would in cases not criminal.

The district attorney held that by so doing she had violated the law, and had even rendered herself liable to punishment in allowing a crazy murderess to wander through the streets.

Judge Mitchell rendered a decision with reference to the case, from which I will quote the most salient points:

"The verdict of the jury is conclusive of the fact of insanity up to the time to which it refers. The fact of insanity was the main fact in issue at the trial; the witnesses gave testimony as to it, the experts gave opinions, the counsel made their arguments pro and con, and the judge in this case expressed plainly his views as to where the weight of the evidence lay. Yet all these were mere preliminaries to the finding of the jury. Whether witnesses or experts, or counsel or judge, agreed or disagreed with the jury, was of no consequence. The jury were the tribunal appointed by law to decide, and their verdict was final and conclusive of the question. The prisoner appealed to this defense, and it served her purpose at the time. She must take the burden with the benefit. The verdict protected her from the penalty of murder, but it also protected society from the danger of her presence until there should be evidence of a substantial change in her condition. No such evidence has been presented in this case. On the contrary, the testimony of the hospital physicians is that the prisoner's state of mind is the same as when they first saw her.

"This case comes directly within the act of April 20, 1869, which provides that where any person is acquitted on the ground of insanity, if the judge is satisfied that the paroxysm of insanity in which the criminal act was committed was the first and only one the prisoner had ever experienced, he may order an unconditional discharge; but, if such paroxysm was preceded by at least one other, the judge may appoint a guardian for the person, taking security for such damage as he may commit, etc., but coupled with the important proviso that, in cases of homicide, or an attempt at homicide, the prisoner should not be discharged, 'unless in the unanimous opinion of the superintendent and managers of the hospital and the court before which he or shed was tried, he or she has recovered and is safe to be at large.' It was earnestly contended by the prisoner's counsel that this act was repealed by the act of 1874, but I cannot concur in that view. This act is conclusive against the prisoner's discharge at the present time. Not only have the managers of the hospital not certified that she is now 'safe to be at large,' but, even if they had, the evidence at trial would compel me to think differently."

In reference to the complaint that the prisoner had been allowed on several occasions to leave the hospital without a keeper, the judge said:

"This was in violation of the order of court, which prescribed 'strict custody.' This order has all the attributes of a judicial sentence. It is an order providing for the custody of the prisoner, based, under authority of the statute, upon a verdict on an indictment for felony. It therefore carried with it, by its own inherent force, the obligation of obedience from those to whom it was directed, and a violation of its terms would not only be subject to the summary jurisdiction of the court for contempt, but, if wilful, would be within the penalty of the criminal law against jailors and other officers permitting an escape. I am, however, satisfied that the violations of the order in this case were the result of misapprehension merely. The law invests the superintendent and managers of insane hospitals with a large amount of discretion as to the liberty to be allowed patients under their care, and the physician in charge failed to appreciate the distinction between the prisoner and an ordinary patient. The distinction, however, is plain and important. As to persons confined under an order of court, the discretion of the hospital authorities must be exercised at all times in subordination to the terms of the order."

He continued:

"In view of the expressed opinion of the physician in charge that this prisoner is not a proper subject for remedial treatment, I am in doubt whether I ought to remand her to the hospital. The subject is full of difficulties. Under the verdict of the jury it would be a violation of her rights to confine her in prison as an ordinary criminal, and there is unfortunately no special place provided, as there should be, for the care of the criminal insane. As the law, however, points out the way in which the original order of commitment may be modified, I leave it for

the present without change. Either the hospital authorities, or the Lunacy Committee, of the Board of Charities, or the District Attorney, may apply for a modification of the order, and the matter can then be fully considered on a hearing where all parties with any interests involved will be entitled to be present or represented. The writ of habeas corpus is dismissed, and the relator remanded."

I was retained with Dr. H. C. Wood, by the District Attorney, to resist the application for the release from the asylum under the writ of habeas corpus, in this case. Neither of us was called upon to give testimony, however, although present in court and acting as advisory experts, because the evidence offered in favor of her discharge was not considered sufficient by the District Attorney to require any special medical opposition. This woman should not have been released. The evidence taken on the trial was not submitted to us. The jury found her to be insane, and acquitted her on this ground. If she were insane at the time of the first trial, nothing was presented during the habeas corpus proceedings to change the grounds for such verdict. Such procedures as were adopted in this case, and also in the recent well-known case of James Nutt, are particularly calculated to bring the plea of insanity in criminal cases into disrepute. I do not say that the plea of insanity was not a good one in both of these cases. I am not now discussing this aspect of the question. It may or it may not have been. In the Emma Bickel case, a person acquitted of a heinous offense, as she had been on this plea, should not, in my opinion, have been released so soon, if at all. Much in her history indicated that, whether sane or insane, she was a dangerous character.

Let me in passing say a few words about the Nutt case. James S. Nutt killed Nicholas Lyman Dukes, the murderer of his father and the defamer of his sister. If ever a killing was justifiable, it was in this case. The counsel who defended Nutt decided to use the plea of emotional or impulsive insanity. Much in the family history of Nutt, and also in the history of his own life, was brought to sustain the view that he was mentally weak or unsound. The circumstances of his father's death, and the aspersions upon his sister, were calculated to unhinge a mind not very strong. Several prominent physicians testified under oath their belief in his insanity. Strong appeals, however, were made to the jury both on the plea of insanity and on the general features of the case. The judge summed up the evidence in what might be considered, under the circumstances, a judicial spirit, although the charge was not of a very positive character. He said, among other things:

"The conclusion I have arrived at is this: In order to acquit the prisoner, the jury must find from the evidence that he was subjected to a power greater than his will. For my part, I have little faith in that insanity which shows itself for a moment and then flies away, leaving no trace behind it. You have no right to infer insanity from the act, but may consider in connection with the killing any peculiarity of action on the part of the prisoner. You have the evidence of expert witnesses, which must be valued as the jury see fit, for they are usually selected with a view to their ability to give favorable testimony, and very often for hire.

"The actual line between sanity and insanity is not easily drawn. This is a serious query for us to face, but we must meet it. You must be careful to distinguish between the act of a sane mind and person and the act of an unsound mind. If you acquit him, you must state that you do so on the ground of insanity. If Nutt has been shown by a fair weight of testimony to have been irresponsible, he should be acquitted. If by a fair weight of testimony he has been shown to be sane, he should be convicted in some degree of crime. The Commonwealth does not demand an acquittal any more than a conviction, but she does demand a just verdict."

The jury, after some hours' consideration, rendered a verdict of acquittal because of insanity. Immediately after the verdict was rendered, one of the counsel for Nutt moved for the discharge of the prisoner. He was, however, detained a short time, and was examined by three or four physicians, who testified that he was now quite sane, and within twenty-four hours of the close of the trial he was set at liberty by order of the court.

Of course, in such cases public sympathy and the sympathy of all honorable men is with the accused, but some other method for justification should be found. It is a farce to bring witnesses to prove through family history and the life history of the individual his insanity, and after demonstrating this, within a few hours prove the person to be sane. While such a course may result in practical justice, and bring about a just retribution, it is calculated to do injury in other cases in which the plea of insanity is properly used.

The insane patient may not only be dis-

charged by the superintendent and management of the hospital, by order of court, and by the various other methods described, but there is in this State at least still another authority, namely, the Committee on Lunacy of the Board of Public Charities. The section defining the authority of this committee in this matter is as follows:

"The Committee on Lunacy may, at any time, order and compel the discharge of any person detained as insane (other than a person committed after trial and convicted of crime, or by order of court), but such order shall not be made unless notice be given to the person having charge of the building in which the the person is detained, and to the person or persons at whose instance the patient is detained, and reasonable opportunity given them to justify a further detention, and the committee shall not sign an order of discharge unless they have personally attended and examined the case of the patient."

This authority has been exercised somewhat frequently in this State during the last year.

Let us next discuss certain questions in reference to the dangers of physicians in connection with cases of insanity. Some of these dangers have become apparent in the discussions in reference to methods of admission and discharge. Physicians are somewhat frequently sued for malpractice, false imprisonment, or on other charges, and are even more frequently threatened with such procedures. In a number of instances in the history of Philadelphia courts, decisions have been rendered against the physicians in the cases.

A recent case and one of some interest is not yet finally decided, although it has been before the courts several times. This is what is sometimes known as the "Haas case." Frederick Haas, an old man, was committed to the State Hospital for the Insane at Norristown, August 31, 1883, on a certificate signed by Drs. A. A. McDonald and Wm. E. Hughes. The superintendent of the asylum refused to keep Haas after he had been at the institution a short time, and the order for his admission was revoked. It was charged that consigning him to the hospital was the result of a conspiracy, in which his wife and daughters and one of the physicians were involved. A criminal suit was subsequently brought by Haas against the physicians. The case was heard before Judge Allison, who, upon hearing the testimony and also the statements of physicians, who, as witnesses, declared their belief in the competency of the gentlemen who signed the certificate, dismissed this criminal suit. Even this did not stop the annoyance to the physicians. A civil suit for damages was brought by Haas and some members of his family against the physicians. It was urged that there was negligence in certifying that the plaintiff was insane. The case was heard before Judge M. Arnold. Dr. Wood and myself testified that the physicians had sufficient ground on which to base an honest belief in the person's insanity. The physicians themselves testified to the examinations they had made, which certainly did not lack in thoroughness so far as could be judged. The case went to the jury, which brought in an extraordinary verdict—one which mulcted one of the physicians in small damages, and allowed the other to go free. The verdict was set aside by the judge, and the case will probably again come up for decision. This case will be sufficient to put you on your guard as to signing such certificates.

I will close with a recent personal experience. About a year ago, in connection with another physician, I made affidavit to the insanity of a business man. The case was to my mind a well-marked example of paretic dementia, or general paralysis of the insane, merging into the middle period of the disease. The man had epileptiform attacks, had disorders of speech, had remarkable delusions of importance and wealth in the shape of great projects, had also delusions of having committed certain crimes, and was subject to violent outbreaks. The examination was made upon the request of the wife and sisters, and personal friends of the individual. He was sent to the Pennsylvania Hospital for the Insane. After being there for a few weeks, he improved, as many of these cases do, temporarily. From the first, of course, he wished to be released, and denounced the physicians who had sent him there. Some members of his family, who had been anxious to have him placed under restraint, became worried about detaining him, owing to his improvement, and they called on me for advice. I told them that I did not believe that he had recovered, and that he had simply one of those remissions which often occurred in the disease, and that if he were discharged he would speedily get into trouble again, and they would have double difficulty in placing him once more in an institution. By his own request, he was visited by lawyers, by members of the Committee on Lunacy, and by a former physician. This physician, a friend of mine, began to think that the patient might possibly be allowed to be at liberty, at least for a time. Finally, he was

discharged. Immediately on being released, he secured the services of lawyers, who seemed ready enough to take hold of the case, and bring a criminal or civil suit, or both, against the other physician and myself. The lawyers made strong efforts to get the physician who had favored the temporary release of the patient to testify in some way against the physicians who had signed the certificate. This he refused to do, stating his belief that they were justified in what they did, and that if suit were brought, he would take the stand in their favor. Numerous efforts of this kind were made without success. In the meantime the evidence of the insanity of the patient again developed and multiplied; he became troublesome, and dangerous to himself and others. Physicians were now called upon to examine and certify to his insanity, but refused, and it was found necessary finally to have a commission or inquisition in lunacy. This was held, and the man again declared insane; and he was sent, by order of the court, to a State hospital, where he now is, a well-marked example of advancing paretic dementia.

COMMUNICATIONS.

ON THE NUTRITIVE VALUE OF SOME BEEF EXTRACTS: AN EXPERIMENTAL INQUIRY.

BY THOMAS J. MAYS, M. D.,

Of Philadelphia.

(*Concluded from page* 582.)

The apparatus which was employed in testing the food value of the beef extracts was the following: The heart, by means of a double cannula, on which it is securely but gently tied, is attached to a Kronecker-Bowditch heart apparatus, and then, through a mercury manometer, and an appropriate glass needle it records its pulsations upon a revolving cylinder. The heart is fed or transfused through the double cannula from two Mariotte's bottles, with any desirable fluid; and in order to keep it pulsating regularly, minimum shocks of one Daniell's cell, through a DuBois sliding induction coil, were employed about every four seconds. Before testing the beef extracts, the heart was in every instance well washed out with a 0.6 per cent. saline solution, after which it was allowed to work with the same until all its stored-up material was exhausted and its pulsations reduced to zero. Then a weak solution of the inorganic elements of the beef extracts, chiefly containing phosphate and carbonate of potash, and chloride of sodium, was carefully tested on the heart to find out whether it had any power to induce cardiac contractions, but it failed in every instance. The same was also found to be true of a solution of urea whenever it was tried. After this preliminary work a number of different dilutions of a beef extract previously prepared with an 0.6 per cent. saline solution (usually in the following proportions: 1 : 100; 1 : 250; 1 : 500; 1 : 666; 1 : 1000; 1 : 2000; 1 : 4000) were alternately introduced into the heart and their effects noted. The stronger dilutions, like 1 : 100 to 1 : 500, had no influence whatever in restoring cardiac contractions; but in every specimen which was examined the dilutions from 1 : 666 to 1 : 2000 had the power of reviving and of maintaining the beats of the heart.

In this experiment the heart was filled with a 0.6 per cent. saline solution and allowed to work with it until it was fatigued, and this was repeated, and the pulse elevations grew after each filling, not because the saline solution conveyed any nutriment to the heart, but because it had not consumed all the energy stored up in its walls. And neither the phosphate of potash nor the saline solution could revive the heart, showing that its whole store of energy was exhausted. Valentine's Meat Juice was introduced and the pulsations grew to about half their original height. The other beef preparations which were examined in the same manner as Valentine's Meat Juice were Reed & Carnrick's Beef Peptonoids, Parke, Davis & Co.'s Sarco-peptones, Johnston's Fluid Beef, Cibil's and Liebig's Extracts, besides milk, and all gave evidence that they possess nutritive properties. Although the amount of nutrition varies somewhat in each specimen, as will appear later on, every one gave tracings substantially similar to those given by Valentine's Meat Juice.

Judging from these data, I think the following deductions can be made concerning the influence of the beef extracts on the frog's heart:

1. That they are absorbed and assimilated.

2. That they contain material which has the power of inducing muscular contraction —a power which has heretofore only been shown experimentally to exist in higher animal albumens or proteids.

3. That, hence, whatever else they may be, they are nutrients in the full implication of that term.

After it was thus demonstrated that these

beef preparations contained definite nutritive properties, it was deemed desirable to ascertain the value of each, and means to this end were instituted by comparing their effects with those of a two per cent. solution of dried bullock's blood alternately on the frog's heart in the following manner: In the first place the heart, after being washed out, was filled with the two per cent. blood solution and then allowed to beat until its pulsations were reduced to a minimum, or until the whole nutritive supply of the blood solution was consumed; after which it was washed out again and filled with a solution of the beef preparation to be tested, and allowed to beat with it until its pulsations were again reduced to a minimum. A large number of comparative tests were made of each of the above named beef preparations in this way, and the following products were obtained, which indicate the mean percentage of the number of pulse beats given by each preparation, while that of blood is taken as 100. These figures are probably not absolutely true, but they give an approximate idea of the nutritive worth of these extracts when compared with that of a two* per cent. blood solution, which is capable of producing a normal cardiac contraction.

	Mean Percentage of Number of Pulse-beats.
Liebig's extract of beef	58
Johnston's fluid beef	59
Valentine's meat juice	60
Cibil's extract of beef	61
Sarco-peptones (Parke, Davis & Co.)	62
Beef peptonoids (Reed & Carnrick)	74
Milk	100
Two per cent. solution of dried bullock's blood	100

From this table, it appears that all these preparations contain very nearly the same amount of nutritive material, except the beef peptonoids, which contain from ten to fifteen per cent. more than the others. It must not be forgotten in this estimation that the beef peptonoids are not a pure beef extract like the rest, but a compound of the latter with milk and gluten. Therefore, in order to get at the true value of this preparation, it is important to test each ingredient. Milk alone gives as good results as the blood solution, as can be seen from the table, and there is no doubt that a portion of its valuable property is due to this agent.

The next question which arises in this investigation is as to which of the many organic bodies resident in the beef extracts this nutritive property is due; and I must confess, that principally owing to the difficulty of obtaining these organic extractives, this portion of the work remains incomplete, but I am making preparations to resume it at an early day. It can be safely stated, however, that the inorganic elements of the beef extracts contribute no share to this result; for the phosphate of potash solution contains all these, and in every instance where this was tested it failed to bring out the least cardiac reaction. Hence, these can be left out of consideration.

When finely divided beef muscle is exposed to the action of about four or five times its own weight of cold water for four or five hours, and then well pressed out, it loses from sixteen to twenty-four per cent. of its original weight. In this watery solution is contained from two to fourteen per cent. of fresh albumen, while the remainder is made up of kreatin, kreatinin, sarkosin, sarkin, xanthin, carnin, inosit, fat, glycogen, and the inorganic elements; while in the residue there is left nothing but fibrous tissue, principally composed of muscular fibres and connective tissue, which is tasteless, rejected by animals, and entirely unfit for nutrition. Therefore, it is very probable that all the nutritive element of beef muscle resides in its organic extractives.

Now there cannot be the least doubt that the variable amount of albumen contained in the beef extracts furnishes some of the nutritive property displayed by them, but it is far from my intention to claim that this is exclusively due to it. Indeed, I have found altogether unexpected indications during the investigation, which may, on further examination, throw some more light on this question. One thing, however, remains steadfast throughout, and that is, if the albumen of flesh is not the sole nutritive element in these beef preparations, then some or all of the organic bodies which they contain must be nutritious, and can no longer be regarded as effete products of the animal body.

It is not necessary to point out, then, that the multitudinous composition of these extracts makes them a very valuable class of alimentary substances, both for nutritive and constructive purposes; and before closing this interesting subject, let me refer very briefly to the practicability of the subcutaneous introduction of these agents. I think it is quite evident now that these preparations are assimilated and utilized by the frog's heart without previously passing through a digestive process, and we have no reason for believing that this does not also obtain in the human organism; hence, in conditions where the stomach has an intolerance of food, or where there is any hindrance to the introduc-

*Two per cent. solution of dried bullock's blood gives as good cardiac contractions as fresh blood in proportion of 1: 3.

tion of the same through the primary passages, the object of feeding the patient can readily be secured by introducing a suitable preparation hypodermically. A number of years ago I treated several such patients with Valentine's Meat Juice, which, on account of its complete solution in the normal state, is probably preferable for this purpose. I injected from fifteen to twenty minims three times a day, with good effects. I failed, however, to keep a record of these cases, but recollect that one was a case of persistent vomiting caused by a severe blow on the head, and that after each injection the patient expressed himself as being stronger and feeling as if he had eaten something. Not the least irritation was produced at the point of injection, and I think this field deserves further investigation.

In conclusion, I wish to thank Dr. Marshall, of the University of Pennsylvania, and Dr. Leffmann, of Jefferson Medical College, for valuable aid in prosecuting these researches.

Medical Societies.

PHILADELPHIA CLINICAL SOCIETY.

Stated meeting, March 26, 1886.

The President, Dr. John B. Roberts, in the chair.

Dr. Edward T. Bruen reported

1. A Case of Abscess of the Liver and Ulcer of the Stomach.

2. A Case of Ulcerative Endocarditis.

These reports will be published in full later.

Dr. John B. Roberts then read a

Report of Two Cases of Abscess of the Nasal Septum.

Abscesses in the septal tissues of the nose are sufficiently uncommon to warrant a report of two cases, especially when both of them were unrecognized when first under professional examination.

1. In 1884, a boy of 10 years was brought to me for difficult breathing, which had occurred subsequently to a fall happening twelve days previously. He had fallen from the top of a stable, striking his face on his knee as he came to the ground, and thereby injuring the nose and lip. The accident was immediately followed by a swelling of the nose and lip, and in the course of a few days by occlusion of the nostrils and snoring respiration at night. When I looked into the nose, I found a soft elevation of the mucous membrane on both sides of the septal cartilage near its anterior margin, from which bleeding occurred upon the contact of the probe. There was no deviation of the external portion or long bridge of the nose. He had had slight delirium one night, according to his mother's statement. I considered the case a fracture of the cartilage with a good deal of swelling, and ordered atropia and iron internally, with the use of boracic acid powder locally. At the next visit I ordered the boracic acid to be used in solution. A few days later I saw him, and incised the pushed-up mucous membrane, evacuating several minims of pus. The abscess had apparently caused perforation of the cartilage, for there existed a communication between the pus collected under the mucous membrane of each side. It is, of course, possible that a fracture had created a communication before the pus was formed. The boy passed from observation; probably because all symptoms were quickly relieved.

2. In December last, a woman of forty years consulted me, saying she had received a blow upon her nose about five and a half weeks previously, but had not been under a physician's care for the injury. A physician, who saw the case before I did, looked upon it as one of deviated septum. I suspected, however, that it might be abscess of the septum, and punctured the swelling which occluded the left nostril by its projection from the surface of the septum. I was rewarded by the escape of some drops of pus. She came back in a day or two, saying her breathing was improved on the left side, but not on the right, which, when I saw her, was not so occluded as the left. Puncture of the septal mucous membrane of the right nostril gave exit to a little sero-pus. Three days later she complained that the left nostril was occluded again, and I accordingly punctured the elevated mucous membrane, and with the fixation forceps used in eye surgery, seized the membrane so that I could clip out a piece with the scissors. Thus I obtained free drainage of the abscess cavity. Subsequently applications of borax and afterwards of a four per cent. solution of cocaine, were applied to both sides of the septum, and the patient was soon cured of the annoying sensation of obstruction which had caused her to seek surgical aid.

CLINICAL SOCIETY OF MARYLAND.

Stated meeting held March 5, 1886.

Dr. W. P. Chunn reported a case of

Kolpo-Cystotomy.

The term kolpo-cystotomy designates an operation for the institution of an artificial vesico-vaginal fistula, and is produced for the relief of chronic cystitis. He first witnessed its beneficial action in a case treated by Professor Wm. T. Howard, where there was much annoyance from frequent micturition, and positive relief from the operation.

Dr. Chunn's case was similar in character. He operated on his patient about three months ago in the following manner. The woman was placed in Sims' position, a sound introduced through the urethra to just within the bladder, a fold of the vesico-vaginal septum was caught up with a tenaculum and the opening made at the most dependent portion of the bladder. The edges of the wound were touched with a solution of persulphate of iron to prevent their primary union; this opening was subsequently kept open by the introduction of a sound once or twice a week. It has now been about three months since the operation was done, and the patient is very comfortable, having been relieved of the annoying incessant dribbling of urine.

Dr. J. H. Branham asked if benzoic acid and tr. belladonnæ, used by Dr. Chunn before the operation, were the only remedial agents employed before resorting to the surgical procedure. He thinks in addition to them benzoic acid should have been given internally, and the bladder frequently washed out with a solution of boracic acid. Also, asked if after the operation the hypertrophied bladder walls had atrophied.

Dr. B. B. Browne said that a very large majority of the cases of cystitis in the female were accompanied by a diseased or morbid condition of the urethral tract, and frequently caruncular growths and fissures exist which keep up an irritable condition of the urethra, and lead to patients retaining their urine for a very long time so as to avoid the pain which they endure while passing it; in consequence of this the bladder becomes overdistended and paralysis of its walls results, the residual urine becomes ammoniacal, and cystitis is set up. In such cases kolpo-cystotomy, of course, would give relief so long as the bladder was drained by this means; but so soon as the artificial fistula was closed the cystitis would sooner or later recur, and continue as long as the previous morbid condition of the urethra exists. From a careful observation and study of a large number of these cases for the past twelve years, he is well satisfied that this is the explanation of the cause and return of the cystitis. He has had perfectly satisfactory results with dilatation of the urethra and removal of the caruncular growths, when they exist. He has never had incontinence of urine follow dilatation, and thinks that the strong statements that have been made in regard to the danger of the operation are more theoretical than practical, as they have only been made by those who condemn the operation and never practice it, and consequently have not much experience with it, whereas others who have dilated the urethra most frequently have had no bad results. As far as the comfort of the patient is concerned, forcible dilatation, which at once overcomes the spasmodic condition of the urethra and allows the woman to retain and pass her urine at will, and free of pain, is certainly preferable to kolpo-cystotomy with subsequent dribbling of urine through the vagina for several months, and then with an almost certainty of the cystitis returning, as in the cases related by Dr. Chunn.

Dr. Browne related several cases of cystitis treated by dilatation and removal of fissures and caruncular growths from the urethra, and referred to a paper on this subject, which he read before the Medical and Chirurgical Faculty, and published in the Transactions of 1880, p. 135.

Dr. Chunn, in replying to Dr. Branham, said he thought his question pertinent, but confessed to not having used the remedies advised by him. He gave as his reason, that the woman had been under the care of several competent physicians at different times, and he took it for granted that *they* had employed the full list of therapeutic agents, to no avail. Moreover, the patient could not be conveniently seen every day, and the case had proceeded to a such decidedly chronic stage that he thought an operation held out greater inducements. In reply to Dr. Browne, he thought dilatation of the urethra gave good results in simple irritability of the bladder, or where there were growths in the urethra or bladder.

Radical Cure of Inguinal Hernia.

Dr. Randolph Winslow, who was to have reported a case of radically cured inguinal hernia, and presented the patient, said he had found upon examining the patient recently that he still had some slight protrusion, although not sufficient to require the use of a truss; he therefore refrained from reporting

it as a case of radical cure of hernia. Thinks had the patient worn a truss for some time time after the operation, that it would more likely have been a radical cure. In performing the operation he had ligated and cut off the sac after the strangulated bowel had been relieved and returned.

Dr. J. W. Chambers asked what effect dissecting out the sac had on the mortality. What were the advantages?

Dr. R. Winslow said as to the mortality, he did not know. Dr. Bull, of New York, had cut off the sac with a view to radical cure, and his patient had died, but thought generally it did *not* increase the mortality.

Dr. R. M. Hall had seen Dr. Richardson, of Boston, operate for strangulated hernia, and asked him if he thought cutting off the sac would result in a radical cure. Dr. Richardson did not think it would.

Meningeal Hemorrhage in the New-Born Child.

Dr. J. H. Branham exhibited a specimen of a brain of a new-born infant in which there had been a meningeal hemorrhage. The child had lived about forty-four hours. There were no symptoms except stertorous breathing and coma just before death. Autopsy revealed a large clot on the right side, the result of the rupture of a small vein near the extremity of the lambdoid suture. A portion of this clot was firm, while the remainder was semi-fluid or fluid.

Dr. R. Winslow: What is thought to be generally the cause of convulsions in the new-born?

Dr. J. H. Branham: Sims ascribed them to meningeal hemorrhage.

Dr. Chambers: Had there been any convulsions in the case under consideration?

Dr. Branham: There had not.

Dr. Winslow thought Dr. Sims had ascribed such convulsions to a displacement of the occipital bone.

Dr. Branham thought that as some of the clot was fluid and the balance firm, it was evidence that the hemorrhage had been slow.

Imperforate Anus.

Dr. H. H. Biedler next reported a case of imperforate anus. The case was that of a boy about three years old, to whom he had been called a few weeks since. He found the patient had been operated on some days after birth with only partial relief, the opening only admitting a No. 8 sound. The patient was suffering very much from intestinal obstruction, as was evinced by an enormously distended abdomen.

He made a perineal incision of about .75 of an inch, into which he passed his finger to the distance of about 2.5 inches. Not being able to make out anything definite, he desisted from further operative procedure. The patient died on the followtng day. Autopsy revealed the rectum to have ended in a narrow fistulous opening about 2.5 inches from where the anus should have been. It was attached by several fibrous bands to the sacrum, and was distended to about eight times in its normal size.

NEW YORK NEUROLOGICAL SOCIETY.

Stated meeting, April 6, 1886.

C. L. Dana, M. D., in the chair.

The following named gentlemen were elected to office for the ensuing year: For President, C. L. Dana, M. D.; for First Vice-President, M. A. Starr, M. D.; for Second Vice-President, B. Sachs, M. D.; for Recording Secretary, G. W. Jacoby, M. D.; for Corresponding Secretary, W. M. Leszynsky, M. D.; for Treasurer, E. C. Harwood, M. D.; for Councilors, L. Weber, M. D., E. C. Seguin, M. D., W. R. Birdsall, M. D., C. M. Hammond, M. D., and A. D. Rockwell, M. D.

A New Thermo-cautery.

Dr. Graeme N. Hammond presented the instrument, consisting of a Bunsen burner, which, by the action of a spring and clamp throwing a platinum tip at right angles to the burner, could at once be converted into a thermo-cautery. It had the advantage over the ordinary Paquelin cautery of being always ready for use.

Case of Median Nerve Suturing.

Dr. Fraser C. Fuller presented a man who two and a half years ago sustained a glass cut wound of the lower forearm, resulting in complete division of the median nerve and a part of the sublimus flexor. The nerve was sutured with three small strands of catgut a few hours after the injury. The tendons were also united. The operation and dressing were absolutely antiseptic, and primary union took place.

At the time of the operation there was complete cutaneous anæsthesia of the region supplied by the nerve. After several months, sensation slowly returned, and a year and a half after the operation it was perfect. Power in the small muscles of the affected hand had not entirely returned.

Dr. Fuller referred to another case, in which spontaneous recovery took place, op-

eration being refused. There occurred, however, deep necrosis of the finger-tips, and to constant care and energetic electrical treatment only could the eventual recovery be attributed.

Dr. Dana thought the case illustrated very well the result of the experiments of Johnson and Stockholm, that divided nerves if sutured healed in about sixty days, but if let alone they healed in about ninety days.

Dr. B. Sachs then read a paper entitled

Preliminary Report on a Case (with Autopsy) of Tubercular Disease of the Spinal Cord.

After a few introductory remarks the reader gave a full report of the case, of which the following is a short abstract:

The trouble, which was supposed by the patient to be rheumatic, began with pains in the left shoulder, which radiated down into the arm, forearm, and hand; by degrees the pain became more intense; for the first it was confined chiefly to the area of distribution of the ulnar nerve, but had gradually spread over the entire dorsal and volar surface of the left arm and hand. In addition to this hyperæsthesia (and hyperalgesia), to puffiness of the fingers and to a glossy appearance of the skin, there was marked weakness of grasp in the left hand, with only slight loss of power in the left upper arm and forearm. The condition of the left upper extremity remained unchanged during the entire course of the disease—a period of about two months. At the time of the first examination—five weeks after initial pains—there were no symptoms discoverable but these: a slight paresis and some hyperæsthesia of the left leg, exaggerated knee jerks, and ankle clonus on both sides. These symptoms, chiefly uni lateral, continued so until the close of the seventh week; meanwhile the paresis of the left leg had developed into almost complete paralysis. In the course of another week this unilateral paralysis was transformed into a complete paraplegia of the lower extremities. The motor paralysis also affected the abdominal muscles, and to some extent the respiratory muscles of the thorax, and the right upper extremity. Incontinence of urine and trophic changes in the skin were superadded. The sensory symptoms amounted to a general hyperæsthesia of the left half of the body below the level of the third rib; this hyperæsthesia was changed toward the end of the disease into an anæsthesia, which spread from the left half and finally involved the right leg, and to a lesser degree the right half of the trunk and the right upper extremity. A tumor pressing upon the left posterior root fibres of one of the lowest cervical segments was thought sufficient to explain the unilateral symptoms; the bilateral symptoms were attributed to a cervico-dorsal myelitis. But there was no clue during life to the nature of the tumor. The autopsy showed a solitary tubercle situated on the left side between the sixth and seventh cervical segments, followed by a cervico-dorsal myelitis; there were *very slight* tubercular deposits in the lungs and intestines.

In his remarks on the case the author of the paper attempted to explain the eccentric characters of the sensory symptoms (no anæsthesia on the side opposite the lesion), the exaggerated knee jerks and presence of ankle clonus on both sides, and then referred in detail to the behavior of the muscular sense, which was lost on the side of the lesion, and not on the side opposite the lesion. This was in accord with Brown Séquard's views, and opposed to those of Ferrier. In conclusion, the reader asked for discussion of the following points: 1. Differential diagnosis between tumor and other forms of spinal cord disease. 2. Frequency of tubercular affection of the spinal cord substance. 3. Unilateral symptoms from spinal cord disease, with special reference to disturbances of sensibility, and of the muscular sense in particular.

DISCUSSION.

Dr. M. A. Starr had, by invitation of Dr. Sachs, made an independent examination of the patient three weeks ago. That which caused them to hesitate in making a diagnosis was the difficulty of harmonizing the sensory disturbances with the assumption of an absolutely unilateral lesion in the cord. It had been said that Brown-Séquard had shown pretty conclusively that anæsthesia on one side and hyperæsthesia on the other were due to a unilateral lesion in the cord on the same side on which there was hyperæsthesia. The autopsy in this case showed pretty evidently that it did not fall in line with those of Brown-Séquard; that in the early stage, at least, of unilateral cord disease, anæsthesia of the opposite side of the body did not always exist. But it was impossible to draw any definite conclusions from a single case, and he had been unwilling to admit this one as being outside the usual line, because he had previously seen one at the polyclinic, since reported by Dr. Taylor as confirming in all respects theory of Brown-Séquard. It was true no autopsy was obtained, but the symptoms seemed to be very definite.

Dr. Starr thought the whole subject of sensory conduction in the spinal cord was in an unsatisfactory state. There seemed to be no doubt that the muscular sense tract lay in the columns of Goll and crossed in the medulla, not in the cord. That view was confirmed by Dr. Sachs's case. The areas of analgesia and hyperalgesia in the later stages of this case were rather irregularly distributed, thus rendering the study of the sensory tracts in the cord extremely difficult. He had been impressed with the great hyperalgesia in the arms of this patient, the slightest touch, even of the nails, causing great pain. If the sensory tracts crossed just after entering the cord, why was there not anæsthesia on the right side in this case? Three or four cases had been recorded in which there was some reason to believe that the sensations were conveyed upward through lateral tracts in the cord, anterior to, and a little outside of, the pyramidal tract. Three or four cases had been reported in which there was ascending degeneration in this tract, and he had himself seen one which was not yet reported. If sensations were carried upward in that portion of the cord, it would possibly explain some of the peculiarities in Dr. Sachs's case in which that portion chiefly escaped.

Dr. L. Putzel said that if Dr. Sachs referred to miliary tuberculosis of the cord he could say from his own experience that it was not of very infrequent occurrence.

Dr. Sachs said he referred to tuberculosis of the spinal cord substance, and not of the meninges.

Dr. Putzel had seen only one case of that kind, in which the disease gave rise to a myelitis with all the symptoms of myelitis. Tuberculosis of the cord had not been suspected. The case occurred in a phthisical woman. It seemed to him that the lesion in Dr. Sachs's case was so diffuse that very little could be learned from it regarding localization and transmission of sensory impressions. Concerning Dr. Starr's views as to the muscular sense being conducted by the columns of Goll, he had seen some years ago a case of meningo-myelitis in which there was considerable thickening of the membranes posteriorly, and such degeneration of the columns of Goll that it could be seen distinctly through the pia mater, yet there was not the slightest evidence of affection of the muscular sense.

Dr. Leo had seen in institutions a number of cases of tuberculosis in patients suffering from locomotor ataxia, especially in old men.

Dr. E. C. Spitzka reviewed some of the points in the case, and said he thought the fact that tumors in other portions of the cord had not been excluded, deprived the case of much determining value as to the views entertained by Brown-Sequard, and referred to in the discussion. He had been somewhat surprised at some of the revelations made during the course of the discussion. He had not considered tuberculosis either of the membranes or of the substance of the cord so common an occurrence in old age that any single observer could have seen a large number of cases, and certainly the suggestion made by Dr. Leo was worthy of following up. Regarding the muscular sense tract, he thought that if a single case were to be accepted as disproving the supposed function of a given part of the cord, there was no part which could not be regarded as without function. He remembered that specimens had been presented before this society in which it was claimed that the columns of Goll had undergone slight degeneration, when it was found that there was only a slight thickening of the septum from old age.

Dr. Putzel remarked that the case which he referred to was also examined by Dr. Welch.

Dr. Graeme M. Hammond said the question which interested him specially was whether exaggerated knee-jerks and ankle clonus necessarily indicated an organic lesion. He had under treatment a gentleman in whom there was exaggerated tendon reflex and very marked ankle clonus in both the upper and lower extremities on the left side. There was no stiffness, pain, atrophy, or other symptoms of spinal disease. After a few doses of ergot the ankle clonus and exaggerated tendon reflex disappeared, to return again after quitting the ergot, and disappearing with its renewal. Two or three years ago he exhibited before the American Neurological Association a man cured of locomotor ataxia, and in whom there was entire absence of the tendon reflex; yet under the influence of ergot the tendon reflex returned. We could hardly conclude that ergot cured true sclerosis or any organic disease. The question arose, were exaggerated reflexes and ankle clonus to be regarded as the effect of organic disease of the cord?

Dr. Putnam Jacobi inquired as to the relation between increased patellar tendon reflex and functional disease, and referred to a marked case of hysteria in which during a protracted attack she noticed very marked exaggeration of the patellar tendon reflex.

Dr. Spitzka said that only a few days ago a child which had polio-myelitis, the right lower extremity only being affected, received for several days in succession double the dose of strychnine which he had intended to administer, which had the effect of producing marked exaggerated knee jerks and ankle clonus, which had previously been entirely absent. He could not understand why ergot should produce the opposite effect, although he did not doubt that it had done so in Dr. Hammond's case.

In taking up the various points raised in the discussion, Dr. Sachs wished to insist again on the importance of differentiating in his case between the symptoms due to the tumor and those due to the subsequent myelitis; the unilateral symptoms alone could be put to the account of the tumor. Addressing himself to Dr. Spitzka, Dr. Sachs said he did not think it was necessary to suppose several lesions in the cord in order to explain the symptoms at the beginning of the case; the symptoms which developed later in the disease were attributed to the myelitis. Of the initial symptoms, the only one opposed to Brown-Séquard's views was the absence of anæsthesia on the side of the body opposide the lesion, and the author explained *that* on the supposition that the fibres in the sensory tract were only pushed aside, and not destroyed by the tumor, retaining their conducting power. Explained in this way, the case could be made to accord with Brown-Séquard's views. As to the exaggerated knee jerks and double ankle clonus, it was admitted by almost all that exaggerated knee jerk might be present in comparatively normal conditions. The existence of ankle clonus without some change in the lateral columns was questioned by many, but it was shown by Prof. Pitres to exist as early as eight hours after an apoplectic attack, and that therefore in his (Dr. Sachs') case it would not be necessary on account of these symptoms alone to assume multiple lesions.

Dr. Sachs agreed with Dr. Spitzka concerning the infrequency of tuberculosis of the spinal cord. The best authorities claimed that tuberculosis of the spinal cord substance was exceedingly rare.

Dr. Leo, in reply to a question, said he did not claim that the tabes dorsalis in the cases which he had seen in old people was due to tuberculosis of the cord; the existence of the two diseases may have been a mere coincidence.

Dr. G. M. Hammond thought that exaggerated tendon reflex or ankle clonus might be due to either a localized congestion or anæmia of the cord, and this would explain why in one case they were relieved by strychnia and in another by ergot.

CHICAGO MEDICAL SOCIETY.

Official Report.

Stated meeting, March 15, 1886.

The President, C. T. Parkes, M. D., in the chair.

Dr. Robert H. Babcock made remarks on

Two Cases of Mitral Stenosis,

with presentation of the patients.

Dr. Babcock said that he did not intend to give any discussion of mitral stenosis, but merely desired to present a few points of interest in connection with these patients. Mitral obstruction is due to a fusing together of the valves so that they project into the ventricle in the form of a funnel, which, according to many authors, is the most frequent form of stenosis; according to others, the obstruction is due to a septum-like valve stretching across the opening, and called the diaphragmatic valve. Owing to the obstruction to the flow of blood from the auricle into the ventricle, a murmur is produced which is rolling or blubbering in character, and, occurring during the auricular systole and previous to the systole of the ventricle, is called pre-systolic or auriculo-systolic. This murmur has been graphically represented by Balfour as in some cases resembling the sound of voot-rrrb, the final t or b being the sudden, abrupt first sound produced by the ventricular systole.

In some cases no pre-systolic murmur, correctly speaking, is heard—only a diastolic murmur which, being loudest at the apex in the mitral area, is a mitral diastolic murmur. This murmur should be differentiated from the diastolic murmur of aortic regurgitation, which, in certain rare cases described by Balthazar Foster, has its maximum of intensity in the mitral area, and not at the centre of the sternum.

In the two cases Dr. Babcock presented, the murmurs differed from each other in character, in the one case the murmur being very distinctly represented by the letters voot, in the other by rrrb. The doctor was disappointed at the last moment by his inability to present a third patient, a man in whom the stenosis was indicated by a mitral diastolic murmur which followed an impure first sound of heart, and both the impure first sound and the diastolic murmur were in this case audible at the lower angle of the

left scapula. The propagation of the diastolic murmur so far to the left is very unusual; indeed, the production of the mitral diastolic murmur is itself very rare, and is probably due to the fact that a rush of blood from the left auricle to the ventricle occurs with greater force at the beginning of the ventricular diastole than during the auricular systole, the auricle being dilated rather than hypertrophied, according to Sansom. The cases were then examined by members of the Society.

Dr. E. C. Dudley reported a

Unique Case of Vesico-vaginal Fistula,

in which the entire vesico-vaginal septum, the vaginal portion of the cervix, and anterior wall of the cervix to the internal os had sloughed away, leaving no bladder tissue between the inner extremities of the urethra and the points at which the vesico-uterine ligaments connect the bladder with the uterus. The only operation which seemed possible was to unite the posterior wall of the cervix uteri with the neck of the bladder. This would turn the uterus into the bladder and necessitate menstruation through the urethra. The anterior wall of the uterus could not be approximated to the neck of the bladder, but it was found, on further examination, that the mucous membrane of the bladder, if caught with the tenaculum about an inch in front of the uterus, could be drawn to the neck of the bladder and held without undue traction. The operator therefore undertook to close the fistula in this way by denuding a strip of the mucous membrane of the bladder from side to side an inch in front of the uterus, and thus he utilized that portion of the bladder between the line of denudation and the uterus, and made it a substitute for the lost anterior wall of the cervix and vesico-vaginal septum. Twenty-two silver wire sutures were employed after Sims's method. Union by first intention followed, notwithstanding the failure of the nurse the third day to keep the catheter *in situ*, which allowed several ounces of the urine to accumulate in the bladder. Notwithstanding the decrease in the size of the bladder necessitated by the operation, the patient experiences no difficulty in retaining the urine all night. The operator is not aware that another case of this kind has been previously reported.

Editorial Department.

Periscope.

A Simple Method of Artificial Respiration.

Dr. John Arthur Francis thus writes in a foreign exchange:

The desideratum at which we aim in artificial respiration, is to obtain a method of as simple a character as possible, combined with the maximum of efficiency. In cases of drowning, especially, many lives would doubtless be saved which are now sacrificed, were the first comers aware of a method requiring no previous practice, and which could be understood from, say, a short paragraph in a newspaper, or a moment's conversation with a friend, without practical illustration. The usual course for bystanders to pursue seems to be to loosen the clothes about the neck, and to vigorously rub the hands whilst some one fetches a policeman, who, in his turn, sends for a medical man. Upon his arrival, the patient is found to be a very fair subject for an undertaker.

In a short note to the *British Medical Journal* in 1884, I drew attention to a method of extreme simplicity, which has been very successful in my hands in many cases of apparently still-born children, and in one very alarming case of chloroform-poisoning. I have great belief that the same means would prove equally efficacious in cases of drowning, both in children and in adults.

The main indications in artificial respiration are, apparently:

1. To loosen clothing, braces, etc., so as to allow free movement of the chest, and prevent constriction of the neck.

2. To bring the trachea, larynx, and pharynx as near as is anatomically possible into a straight line with the openings of the mouth and nose.

3. To obtain as deep an inspiration as possible by elevating the ribs and depressing the diaphragm; and,

4. To get a deep expiration.

Now, although the accepted modes of

restoring respiration have proved very successful in the hands of medical men, the trained staff of the Humane Society, and doubtless many policemen, etc., yet I think they are almost unknown to the general public, who have not attended ambulance lectures. What we require is that an efficacious method should be as well known and as easily learnt as the fact that a poultice is a proper application for a boil.

What I claim for my improvement is, that it would soon be understood by the laity, and that it fulfils the last three indications mentioned above more thoroughly than the present accepted methods.

I remember, in two cases of drowning where I was sent for, watching a couple of policemen attempt the Marshall Hall proceeding. As the subjects had been submerged for eight and four hours respectively, I did not interfere. In both cases, the chin was on the chest, and the mouth and nose obstructed by the arm in the semi-prone position. This appeared to me a thing to be avoided. The Sylvester mode, adopted by the Royal Humane Society, is an improvement; but I think that the bundle of clothes under the neck is a mistake, as it is apt to slip up and throw the head forwards; and that the proceeding to procure inspiration acts in no way on the diaphragm, whilst a great deal of expansion of the chest is lost by not making use of the weight of the arms and ribs, combined with an extended spine.

Howard's is a still further improvement. The bundle under the back extends the spine and raises the ribs and sternum, at the same time that the intestines gravitate from the diaphragm and tend to cause inspiration by depressing that muscle through the alteration of the pressure in the lungs. But, in this case, the advantage of a good deep expiration, which seems to me of nearly equal importance, following the admission of air into the chest, is lost or rendered less by the bundle of clothes, which keeps the ribs permanently raised. His plan of kneeling across the abdomen, and springing backwards with the hands on the thorax, though apparently very successful in experienced hands, seems to present elements of danger, should it be undertaken by a heavy, clumsy, and inexperienced man.

Now, I believe that my method combines all the advantages of the above in a greater degree, without the disadvantages attending them; and also possesses the required simplicity. It is, merely, the body having been laid on the back, with clothes loosened and the mouth and nose wiped, for two bystanders to pass a narrow lever of any kind under the body at the level of the waist, and raise it till the tips of the fingers and the toes of the subject alone touch the ground; count fifteen rapidly; then lower the body flat to the ground, and press the elbows to the sides hard; count fifteen again; then raise the body again for the same length of time; and so on, alternately raising and lowering. The head, arms, and legs are to be allowed to dangle down quite freely when the body is raised. A child can easily be manipulated by one person with a hand under each loin. For an adult, the best way is for two persons to grasp each other's right hand under the body, and then raise it. A stout walking-stick or umbrella would be efficacious where the operators were too weak to lift up the patient with one clasped hand. To join both left and right hands with those of another person, would probably form too great a plane for the body to rest on, except in the case of a very tall patient, and prevent the full extension of the spine.

With regard to the tongue in suspended animation, I am inclined to believe that the danger of the tongue obstructing the entrance of air to the lungs is somewhat exaggerated; at least, in children I have never observed any necessity for interfering with that organ, and the air has apparently passed through the nose in preference to the mouth, and that quite freely. Although, of course, medical men would use their own discretion in such a matter, according to the exigencies of the case, yet I think it would be wiser for ambulance books, etc., not to instruct the public to pull out the tongue. An ignorant person would probably interfere greatly with the attempt at artificial respiration, would very likely close up the mouth by holding the tongue against the upper jaw, and finish the case by obstructing the nostrils with the palm of his hand.

Of course, in addition to my method of respiration, other aids are not to be neglected for restoring the circulation, such as hot brandy and water, when the patient can swallow, etc.

It seems to me that the position of the body, when raised as described, mechanically puts upon the stretch all the muscles of inspiration, except the external intercostals, and that the position of the ribs, sternum, and clavicles, allows their weight to aid considerably in the expansion of the thoracic cavity. The intestines and abdominal viscera also gravitate towards the pelvis, and would doubtless draw down the diaphragm.

Sudden Death from Hemorrhage into the Abdominal Cavity During Menstruation.

Dr. Edmund J. Penny thus writes in the *Brit. Med. Jour.:*

At 4 a. m., on November 11, 1885, I was summoned to R. E. T., aged 27, a resident of Hayes, Middlesex, who was said to be very ill. Within ten minutes I arrived at the house, and found that life was extinct, with all the signs of collapse present. Her husband stated that she had always enjoyed good health, and was the mother of two children. She was perfectly well until about 7 on the previous evening, when she complained to him of pain in the region of the stomach, which she attributed to the fact that she was menstruating at the time, and said she thought she would go to bed. She gradually grew worse, was extremely restless, complained of pain in her chest, and of difficulty of breathing; but refused to allow medical aid to be summoned, as she said she would be better in the morning.

Shortly before 4 a. m., her condition becoming more serious, my attendance was requested; but the patient had already died during her husband's short absence.

A necropsy was made on November 13, by Mr. E. J. Parrott and myself. The body was well nourished. Rigor mortis was present. The surface was unusually blanched. There were well-marked blood-stains to be seen at the external genitals. The lungs were found to be healthy; the pleura was normal, and the pleural cavity contained its natural quantity of serum. The pericardium was natural, with the usual amount of fluid. The muscular tissue of the heart was healthy. The ventricles were contracted; there was a small clot of fibrin in the left ventricular cavity. The valves were healthy. After the thoracic viscera were removed, the diaphragm was seen to bulge upwards in an unusual manner, particularly on the right side. On opening the abdominal cavity, a large quantity of dark fluid blood immediately escaped, and the whole of the right side of the abdominal cavity was found to be full of fluid and semi-coagulated blood; while the right iliac fossa was occupied by a tolerably firm clot, of the size of a fœtal head. The viscera were carefully removed and examined, and were found to be healthy, with no trace of lesion. The aorta and its principal branches were also minutely examined, and found to be everywhere healthy, nor could any lesion be discovered in the veins. On removing the large clot from the right iliac fossa, and tracing it onwards, it was found to lead to the right ovary; and a small but firm clot, at least an inch in length, was discovered attached to the outer surface of that organ. Two ruptured Graafian vesicles were also seen, to one of which an ovum was adherent; and in the neighborhood of these, several small blood-vessels were found to be distended with clot, one of them being distinctly ruptured; and it was to this site that the clot above-mentioned was found to be adherent. The left ovary also showed signs of activity having taken place previously to death; and on its surface were seen small blood-vessels filled with clot, whilst an ovum was also attached to it. The uterus, which not removed, appeared to be normal.

The occurrence of hemorrhage into the abdominal cavity, due to the rupture of a Graafian follicle during menstruation, is undoubtedly rare; but it is, notwithstanding, admitted by various writers on obstetrics, and notably Dr. Graily Hewitt. Hemorrhage, in this case, evidently took place very slowly, occupying at least nine hours, while the quantity of blood extravasated was enormous.

It seemed as if the whole body had been drained into the abdominal cavity; and the facts above stated, to our minds, so clearly indicated the ovaries as the seat of the hemorrhage, that I had no hesitation in stating such to be the cause of death at the coroner's inquest.

A Complicated Labor.

Dr. John D. Skeer thus writes in the *Chicago Medical Journal* for March:

Mrs. H., æt. 27, American, primipara. Labor began at 1 a. m. on September 1, 1885, and at 7 a. m. her family physician, Dr. E. Wyllys Andrews, was sent for. On arriving he found the os uteri slightly dilated, but could, however, make out a vertex presentation. Labor progressed from that time naturally, but slowly, until 3:15 p. m. of the same day, at which time a living, well-formed child was born. Immediately Dr. Andrews discovered the presence of a second child in the cavity of the uterus. The pains had ceased, and after waiting a half hour, a small dose of the fluid extract of ergot was administered, which was repeated at the end of an hour. These methods failed to excite the slightest uterine contractions. At 5:30 p. m. I was called in consultation.

We found it very difficult to make out the presentation, which proved to be the tuberosity of the right ischium, occupying the middle of the superior strait. The child's pelvis was tipped toward the mother's left

side. An undetached placenta occupied the left iliac fossa, extending nearly to the os uteri.

As there was no hemorrhage, we waited an hour and gave more ergot, but the pains continued to be irregular and inefficient, and we decided to bring down the feet and deliver at once. On introducing the hand, but one foot and one arm could be felt, the latter inclined to fall down in the pelvis. In the position that should have been occupied by the left leg and arm a large fleshy mass could be felt without any definite outline. The right leg was brought down with the toes to the front, and traction was made without causing the slightest change in the position of the child—it was firmly fixed, and held as though in a vise. Strong, unremitting traction for about half an hour, at the same time rotating the child toward the mother's left side, brought the child's pelvis through the vulva with the heel to the front. The child was then delivered as an ordinary breech presentation, and was found to be well developed, dead, and not a monstrosity as was at first supposed.

As the placentæ were not expelled within an hour, the cords were traced upward; one led to the lower placenta, the other was traced upward through a small opening beyond our reach. We then realized for the first time that we had an hour-glass contraction of the uterus, which had taken place after the delivery of the first child. With careful bi-manual palpation the constriction was overcome, and the upper after-birth removed. It was adherent throughout its entire extent. Immediately after the removal of the upper placenta the lower one became detached, and was readily brought away. The placentæ were united by a strong fibrous band about six inches in width. The patient made a good recovery, and nothing occurred in the after-treatment worthy of note.

Conclusions.—Regarding the position of the second child, we had, below the constriction, the body, the right arm and leg, and, as it proved, the left thigh and leg. For on no other hypothesis can we account for the oblique position of the pelvis, unless the foot were grasped and held in the upper chamber by the contraction. The left thigh and leg were behind and completely covered by the membranous band uniting the placentæ, so that their position could not be determined. Rotating the child towards the mother's left, slipped the left thigh and leg from behind the band, without detaching the after-birth. Had this latter accident happened, hemorrhage would have been a serious, if not fatal, complication.

A Case of Imperfect Abortion; Sapræmia; Recovery.

Dr. W. S. A. Griffith thus writes in the *Brit. Med. Jour.*:

The following case illustrates the dangers of imperfect abortion, and the satisfactory results to be obtained when the usual method of treatment is thoroughly carried out.

M. A., aged 45, the mother of thirteen children, the last five years old, came to the out-patient room at the Samaritan Hospital, complaing that she had not been well since her last miscarriage, twelve months previously; since then, she had suffered from profuse menorrhagia, and, for the last two months, a continuous bloody discharge, now fœtid, with bearing-down pains, which had obliged her to give up work, much against her will.

On vaginal examination, the uterus was found much enlarged, retroflexed, and the cavity so open as easily to admit a finger to the fundus. The cavity was occupied by blood-clot and a mass of decidua, which was adherent only to the anterior wall and the fundus. The hemorrhage after this examination was so considerable, that it was determined to remove the mass immediately; and, without much difficulty, this was done, the anterior lip of the cervix being seized by a valsellum forceps. The uterus was then gently irrigated with hot water, to which a little tincture of iodine was added, and the patient sent to the ward at the Dorset House branch.

Two hours later, the patient, who had had rigors, was found to have a temperature of 105°, and a large-volumed pulse of 128; the skin was very hot, and she complained of intense thirst.

The uterus was still patulous, and contained blood-clot, which, with two minute fragments of decidua, was removed; the uterus was again thoroughly irrigated, and a tampon of wool, smeared with iodoform and eucalyptus-vaseline, inserted into it. Six grains of quinine were given; and a draught containing a drachm of the liquid extract of ergot, and two grains of quinine, was ordered to be given twice that evening, and three times a day afterwards. Two hours later, the temperature had fallen to 102°, and, an hour after, to 101°, and the pulse to 100; she was sweating profusely, and was much more comfortable.

The following morning the temperature was 99°, and the pulse 84; the tampon was removed from the uterus, and another inserted into the vagina.

From this time, convalescence proceeded uninterruptedly, and involution of the uterus,

which had been delayed for twelve months, rapidly took place; the uterus became rigid, and was no longer retroflexed, and, on the fourth day, its cavity measured barely three inches. There was no hemorrhage after the uterus was once completely emptied.

The rapidity with which involution took place precludes the probability of there having been any chronic metritis set up by the prolonged retention of decidua; and, except at the seat of attachment, the mucous membrane of the uterus appeared to be natural, and free from inflammation.

Sapræmia is believed to be a septic condition produced by the absorption of septic material, which, unlike that causing septicæmia or pyæmia, has no power of growth and propagation in the blood, and, therefore, produces effects only in proportion to its amount; and when, as in this case, its source is easily within reach, and the septic matter can be readily and completely removed, it is most amenable to antiseptic treatment.

Case of Protracted Mechanical Labor Followed by Diphtheritic Inflammation of the Parturient Canal.

Dr. John E. Hall thus writes in the *Albany Med. Annals:*

June 24, 1881, I was called to attend Mrs. J. K., in her first confinement. She was a lady of medium build, dark hair and skin, age 30, born in Troy. Her labor was a little harder than the average, so that after having been with her some six hours I applied my small forceps, and she was very soon delivered of a strong, healthy boy, weighing about nine pounds. She progressed well for two or three days, with the exception of an unusual amount of pain in the abdominal region and a slight rise of temperature. On the fifth or sixth day her temperature rose to 105¼°, with excessive pain in the abdomen. A vaginal examination revealed extensive metritis, and the vaginal walls largely covered with a complete diphtheritic membrane.

This occurred in the early days of July, with the atmospheric temperature at 90° every day, and the patient lived in ar upper floor under a flat tin roof. I took the patient's temperature three or four times a day for thirteen days in succession; for six consecutive days her temperature was not less than 102¾°, and never above 105¼°; pulse from 110 to 130. During this time she was unable to pass urine, and on one of these days I drew off over sixty ounces. I shall never forget the condition in which I found her as I entered the room about 5 p. m., July 4th. She was lying in a small bed-room situated in the southwest corner of the house, gasping from the excessive heat of the day, and fatigued with the noise of twenty or thirty boys playing near her window. The exhaustion was so great that death seemed to be very near. I immediately pulled off my coat and remained with her two to three hours, and by the use of ice-cold cloths and whisky I was able to leave her in a more favorable condition. The progress for the next ten days was gradual, and she was confined to her bed for the entire month of July. She rode out for the first time on the 10th of August.

From July 1 to 10 there was excessive diarrhœa, which was treated by hypodermics of morphia and enemata of laudanum and starch. The local treatment consisted of carbolized injections of warm water every three or four hours. Internally, milk punch and other supporting measures.

She made a good recovery, and has since borne children with no such unpleasant complications as with the first.

As to the origin of the diphtheritic poisoning: I had not had a case of diphtheria for months, as far as I could remember. I used only those instruments that I had been and am still using, and had never had a similar case before or since that date. Hygienic surroundings were good. I do not think there had been a case of contagious disease in that proximity for several weeks.

Russian Diuretics.

The Russians have great faith in diuretics, and therefore many drugs of this class are popular as household remedies. Some of these, such as fox-glove, were in use amongst the peasants long before they were admitted into the category of even extra-pharmacopœial remedies prescribed by professional men. Dr. S. A. Popoff has recently made some researches on the action of certain household diuretics, communicating his results to the recent congress of Russian doctors. Cloudberries (rubus chamæmorus) are almost unknown in scientific medicine, though a paper on their diuretic quality was written in 1856 in German by Dr. Trinkovski, who recommended them in hydrocephalus. Dr. Popoff prepared infusions, decoctions, and tinctures, and also an acid which he believes to be the active principle, and found, by experiments on animals, that considerable increase in the urinary secretion was produced by the administration of any of the preparations by the mouth, under the skin, or into the veins.

This occurred also when the spinal cord and the splanchnics were divided, and when the animal was under the influence of curare. There was no alteration in the blood-pressure, and but slight palpitation of the heart. The only cases in which any slowing of the heart occurred were those in which a solution of the acid was introduced directly into the jugular. Nikanoroff's experiment of causing defibrinated blood to circulate through the kidney, first alone and then containing the acid in solution, was tried, and the amount of blood flowing out of the renal veins determined, but no positive results were thus obtained. The author has no doubt that the cloud-berry acts by directly stimulating the renal tissue without acting on the heart or circulatory system. It has thus, he says, an effect similar to that of antihydropin (tincture of black-beetles), which is well known in Russia and prescribed frequently, but this latter has the more powerful action of the two.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——An interesting address on the water supply of cities and villages, by Dr. A. Vanderveer, has been separately published from the Transactions of the Medical Society of New York. It presents the subject in a brief and pointed manner.

——"The Æsthetics of Medicine," is the title of a reprint by Dr. H. A. Cottell, of Louisville. It is in the nature of an address, and presents the subject in a pleasing way.

——The management at Sharon Springs, New York, has published a pamphlet describing the methods in use at that establishment for the treatment of nasal catarrh.

——A careful study of typhoid fever in Philadelphia, by Dr. Henry Leffmann, a reprint of which is before us, shows that that disease is steadily on the increase in this city, and endeavors to discover the cause.

——Several suggestive studies on nasal catarrh have lately appeared in various journals from the competent pen of Dr. Harrison Allen, of Philadelphia. One of these treats of the headaches which are associated with this condition; another on digital examination of the nasal chambers; and a third on the connection between obstruction of the lachrymal duct and nasal catarrh.

BOOK NOTICES.

A Compend of Pharmacy. By F. E. Stewart, M. D., Ph. G., etc. 12mo; pp. 196. Philadelphia, P. Blakiston, Son & Co., 1886.

This publication belongs to the "Quiz-Compend" series, which have been issued by the publishers with considerable success. They are generally carefully compiled and have been popular with students. The present work is based, by special permission, on Prof. Joseph P. Remington's "Text-Book of Pharmacy," which is now the acknowledged standard authority. The author and publishers have given much time towards making it as complete and concise as possible, and in arranging the types and paragraphs so that it may be easily and quickly referred to, and it will be found a useful guide to the tyro and worker in pharmacy.

The Student's Manual of Venereal Diseases. By Berkeley Hill, M. D., and Arthur Cooper, M. D., etc. Fourth edition. 12mo.; pp. 130. Price, $1.00. P. Blakiston, Son & Co., Philadelphia.

A concise account of the venereal affections is here presented, just enough to give the reader or student a correct outline of their history, methods of contagion, manifestations, sequelæ, and treatment. Those mentioned are syphilis, chancre, gonorrhœa, and their accessory disorders and complications. Within the space allotted to these large topics the authors have done better than could have been expected. This fourth edition has undergone careful revision.

On Asthma; Its Nature and Treatment. Containing an Entirely New and Comprehensive Working Hypothesis. By Horace Dobell, M. D. Illustrated. Smith, Elder & Co., London, 1886.

The name of Dr. Horace Dobell has long been associated with many interesting researches into the pathology and treatment of diseases of the respiratory organs. In the essay before us he presents with much care and elaboration a theory of the phenomena of asthma, and a variety of suggestions as to its treatment. One of the most noteworthy of the latter is the anhydrous oxide of barium. This active substance he suggests on theoretical grounds, and does not offer clinical examples of its efficacy. There is a large double-page colored illustration, which shows graphically the scheme of the author's theory of the action of the nerve forces in asthmatic paroxysms.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

THE EFFECT OF THE REMOVAL OF THE SPLEEN ON THE BLOOD.

At the January meeting of the Petersburg (Russian) Medical Society, Dr. Motschutkovski, of Odessa, presiding, Dr. Winogradow made the report of a very interesting experiment. Six years before, the spleen had been removed from a dog, and the blood was examined after that period to determine any possible alterations which the blood might have suffered in consequence of the removal of an organ so universally supposed to play an important part in the manufacture of the circulating fluid.

For the experiment a dog had been selected which thus far had been roaming about without a protective roof at night, and with but rare food, such as the animal was able to pick up on the street. After the splenotomy, the dog lived in good air, attached to a chain, nourished by mixed good food, and in possession of a warm shed, that gave him protection against inclement weather, and which was kept plentifully provided daily with fresh straw.

The examination of the blood gave the following result: During the first year after the operation a steady increase of the serum of the blood was observed, which augmentation continued until August, 1885, after which date the watery portion of the blood slowly once more diminished, until it reached the normal quantity, such as usually met with in dogs *with* a spleen. This normal state then remained. The number of red corpuscles increased in the second and third years after the operation, then it diminished, and the microcytes also have become less during the most recent period.

The specific gravity of the blood (1054) as well as of the serum (1026), always remained normal. The quantity of the hæmaglobin, which had decreased at the end of the first year, and but little varied during the other years, has of late again diminished.

Of all the phenomena noted, the diminution in the production of hæmaglobin is the most noteworthy. Very soon after the operation the production appeared even more active (in consequence of better food and better hygienic conditions?), but remained all the time below the normal, and during the last year it has become steadily less; from which fact Dr. W. draws the conclusion, that the compensatory action of the other blood-manufacturing organs gradually ceases, and that the animal will probably die in consequence of the steadily diminishing quantity of hæmaglobin, for even now the dog is slowly losing in weight, notwithstanding good nourishing food, best care, and a pure atmosphere.

TUBERCULOSIS OF THE BUCCAL MUCOUS MEMBRANE.

There are four different ulcerations which may attack the buccal mucous membrane. All four are of a grave nature, but one, if early recognized and correctly treated, may be cured, provided it has not yet impregnated the whole system. These four are carcinoma, lupus, syphilis, and tuberculosis. Mr. David Hausemann, of Kiel (*Virchow's Arch.*, 103 bd., 2 heft, 1886), has recently drawn our attention to these ulcerations, and published the result of his investigations.

According to him the main point, the correct diagnosis, can only be made by excision of the new growth and later examination of the same under the microscope. For this purpose, while the presence of giant cells with granulation tissue might answer in a general way, the discovery of the tubercle bacilli forms alone the definite proof; but of late it has been made so easy to detect their presence that almost a tyro in the art, provided his microscope be powerful enough, can demonstrate their existence. The tubercular nature proved, a thorough excision will establish a radical cure, provided the system is not yet affected, *i. e.*, provided there is no dullness over the apex of one lung.

Lues can generally be excluded by noting for one or two weeks the effect of specific treatment, as under the latter any syphilitic sore would at once improve. While the diagnosis between cancer and lupus is easy, that between the latter and tuberculosis is more difficult, as the bacillus of lupus and that of tubercle greatly resemble each other. Here the pure-culture, or at least the color-test, will decide.

The advantage to be obtained from following H.'s advice is clear, as an early excision of the tubercular growth will prevent a return and a general infection, while of the other malignant growths such cannot be said with the same certainty.

THE INTERNATIONAL CONGRESS.

It will be seen from the report that we elsewhere publish, that the American Medical Association has decided not to make any alteration in the organization of the International Medical Congress. This being the ultimatum, we trust that the profession, as a body, will accept it with good grace.

—Dr. William S. Little returns home much benefited in health from his winter sojourn in Thomasville, Ga.

Notes and Comments.

Case of Traumatic Nephrosis.

Before the Medical Society of London, Dr. John Lowe read the notes of a case in which the patient, a healthy, robust young man, was run over by an empty wagon, the wheel passing over the abdomen. Some weeks later a tumor formed in the right hypochondrium, which yielded distinct signs of fluctuation and fluid vibration. There was no albumen in his urine, no history of hæmaturia, nor any distinct jaundice. The tumor was slightly tender on pressure. The opinion was in favor of its being a renal cyst, resulting from injury to the ureter. Dr. Lowe introduced a moderate-sized trocar, and withdrew nine pints of fluid, which deposited a copious precipitate on the application of heat, the precipitate not being soluble in nitric acid. Subsequently, even larger quantities were evacuated, and tincture of iodine was injected into the sac. The area of dulness and the circumference of the abdomen gradually diminished, and he was finally made an out-patient, ultimately resuming his laborious occupation on the railway, without inconvenience. The diagnosis rested mainly on the following points: 1. The rapid formation of the tumor soon after the injury. 2. The highly albuminous character of the clear fluid withdrawn. Several other cases are on record where tapping had been attended with success, although it is not easy to see exactly why this was so.

Mr. Bernard Pitts mentioned the case of a girl who had been run over by a hansom cab. There appeared to have been some hæmaturia; and six weeks later a tumor was found, which was tapped, and about thirty-one ounces of clear fluid withdrawn. The sac rapidly refilled, and massage was then resorted to, with the result of procuring ultimate arrest and diminution in the size of the tumor.

Mr. Walter Pye quoted the case of a man who had been wounded by a spear thrust, involving the kidney. About a fortnight later hydronephrosis developed, and was tapped; sixty ounces of a clear albuminous fluid being evacuated. There has been no recurrence. It was probably caused by plugging of the ureter with blood-clot, the result of the injury to the kidney.

Mr. Davies Colley recalled an incomplete but interesting case of hydronephrosis, attributed, by the patient, to the shock of a railway accident. An action was brought against the railway company, and some division of

opinion was elicited as to the influence of the shock in the production of the tumor. His own opinion was that a calculus had probably become displaced, and so caused the blockage.

Dr. Samuel West said that, to his mind, the evidence was inconclusive as to diagnosis of hydronephrosis, and suggested that some of the symptoms pointed rather to chronic peritonitis with effusion.

Dr. Lowe, in reply, said that plugging by means of blood-clot was a very probable cause, and he said that injuries to the kidneys, involving hæmaturia, were more common than might be supposed.

Effects of an Extensive Fracture of the Skull.

A case of extensive wound of the skull and brain is reported in the Russian *Herald of Forensic Medicine.* The patient was a man who had been struck by a piece of an anvil of about seven pounds' weight. The wound extended from half an inch above the concha of the left ear to the right parietal eminence. The fracture of the skull corresponded in length and position with the external wound. In many places it was splintered, the posterior edge of the fracture being raised above the level of the anterior edge. The whole wound was filled with crushed brain substance, partly gray and partly white. There was both motor and sensory paralysis of the right arm. The power of sensation in the right leg was diminished; the pulse was 80 and the respirations 20; the temperature was also normal. The patient was fully conscious and in a peculiarly placid state of mind, being pleased with everything. He forgot, however, a number of abstract nouns and all proper names; his memory for numbers was also affected, and he had forgotten how to read. The wound was dressed with antiseptic bandages, and completely healed in fourteen weeks. During this time ten splinters were removed. The symptoms of amnesic aphasia gradually passed off. The memory for abstract nouns returned in about a fortnight. The placid humor passed away, and the man became decidedly irritable, and suffered from insomnia and headache. The paralysis of the leg passed off during the first few weeks. Sensation returned in the arm, and movement also, and after three months contraction occurred. After the lapse of eight months the man was still unable to read, and complained of constant headache and great feebleness of memory.

Erythema Nodosum.

The eruptive affection denominated erythema nodosum has always presented enough obscurity as to its etiology and relations to render it an object of peculiar interest to all observing physicians, and many persons will welcome the attempt made by Dr. Stephen Mackenzie to discover something definite regarding it. Dr. Mackenzie communicated the result of his inquiry to the Clinical Society of London recently, and though he is hardly yet to be congratulated on having cleared away all uncertainty surrounding our knowledge of the disease, yet he has unquestionably increased our knowledge respecting it. The most prominent point brought out by the paper seemed to be that, erythema nodosum is in some way associated with the rheumatic diathesis, not, as Dr. Mackenzie was careful to explain, that it can be regarded as in any way causative or rheumatism, but that its occurrence is strongly indicative of a tendency to the development of rheumatic affections. An important suggestion was made by Dr. Mackenzie to the effect that heart disease might be directly associated with the erythema, even in the absence of rheumatism, as evidenced by joint troubles, etc.; though this opinion did not approve itself either to Dr. Carrington or Dr. Angel Money. Other suggestions made in the paper likewise came in for criticism, but the main conclusion remains unchallenged, that, viz., that there is an intimate relation of some kind between rheumatism and erythema nodosum. The paper will serve to animate and direct further researches in the same direction.

Hemicrania of Eighteen Years' Standing; Cured by Operation on Old Laceration of Cervix and Pelveo-abdominal Galvanization.

Writing about reflex genital neuroses in the *Journal of Nervous and Mental Diseases,* Dr. Paul F. Mundé relates this case:

Mrs. C. S., thirty-nine years of age; married twice; one child by first husband eighteen years ago; married seven years to second husband without conceiving. Complains of frequent pain in right groin and down right thigh, with right hemicrania, nausea, and vomiting, both of which symptoms are most marked before the menstrual flow. Examination showed a bilateral laceration of the cervix of the third degree, completely healed over; extending from the angle of the rent in the right side was a small, hard nodule, evidently an old plastic

exudation, pressure on which caused pain down the right thigh. Basing on a previous good result from galvanism in acute sciatica due to pelvic exudation, but without expecting any benefit to the hemicrania, I applied galvanism by a vaginal electrode and a sponge over the right ovarian and sciatic regions, with the result of not only relieving the sciatica, but, curiously, also the hemicrania, the attacks of which diminished in frequency and severity after several weeks of galvanization, and finally ceased entirely The cure was confirmed by excising the cicatricial tissue in the angle of the cervical tear and uniting the edges. The patient has since then (nearly five years) remained free from sciatica or hemicrania.

Hemiglossitis.

Dr. R. Demme reports (*Wiener Medizinische Wochenschrift*, No. 7, 1886,) a case of a child, aged six months, whose tongue became rapidly swollen, so that it projected from the half-opened mouth. Examination showed that the swelling was confined chiefly to the right side, the surface of which was covered with yellowish-white vesicles, from the size of a millet-seed to that of a pin-head, arranged in groups. Similar vesicles were visible also on the inner and outer sides of the right cheek. On the fourth day the swelling subsided as rapidly as it had come, and the vesicles dried up and disappeared. From the similarity in symptoms and course of the disease to those of herpes zoster, the writer regarded it as a form of this affection. Two similar cases, occurring in adults, are reported by Dr. P. Güterbock (*Centralblatt für Chirurgie*, No. 7, 1886). In both of these cases, also, the affection was confined to the right side of the tongue. In these and other cases the seat of the disease corresponded almost exactly to the area of distribution of filaments of the trigeminal nerve, and in some reported instances there seemed also to be a participation of the chorda tympani in the disturbance. The glosso-pharyngeal and the hypoglossal nerves, on the other hand, seemed in none of the cases to have any etiological relation to the affection.

Alcoholism.

Dr. Jas. C. Wilson (*Polyclinic*, December 15, 1885,) makes the following division of alcoholism:

I. Acute alcoholism—
(A) Ordinary typical form.
(B) Irregular forms.
1. Maniacal.
2. Conclusive.
3. In persons of unsound mind.
(C) Acute poisoning by alcohol (lethal dose).

II. Chronic alcoholism—
(A) Visceral derangements.
1. Local disorders. *a.* Of the digestive system. *b.* Of the liver. *c.* Of the respiratory organs. *d.* Of the circulatory system. *e.* Of the genito-urinary apparatus.
2. Disorders of special structures. *a.* Of the locomotor apparatus. *b.* Of the skin.
(B) Derangements of the nervous system. Cerebro-spinal disorders.
1. Cerebral disorders. Complications. *a.* Lepto-meningitis. *b.* Pachymeningitis. *c.* Epilepsy. *d.* Cerebral congestion. *e.* Cerebral softening. *f.* Sclerosis.
2. Spinal disorders.
3. Disorders of the special senses.
(C) Psychical derangements.
1. Alcoholic delirium in general.
2. Delirium tremens.
3. Alcoholic psychoses.

III. Hereditary alcoholism.

IV. Dipsomania.

True dipsomania is not a manifestation of alcoholism, but a periodical insanity. The relations of alcohol to it are symptomatological, not ætiological.

A Case of Narrowing of the Small Intestine.

This case, which Dr. Davidson reports in the *Med. Press*, was one of a boy, æt. 5, the constriction being organic, and the passage less than half an inch in diameter. The situation was barely an inch from the ileo-cæcal valve. It was probably caused by the appendix lying across the small intestine at this point, and so leading to a gradual narrowing of the bowel.

The child had no symptoms of obstruction till ten days before admission into the Infirmary, when constipation and vomiting commenced. On admission the abdomen was much distended and tympanitic, pulse 120, temp. normal. He was treated with tinct. bellad. ♏v. every four hours, and small quantities of beef tea and barley water. The vomiting ceased soon after admission, and bowels acted the same evening. The child continued to improve, but suddenly, a fortnight after admission, was seized with symptoms of acute peritonitis, without any apparent cause, and died the same night. At the post-mortem a perforation of the bowel was found close to the stricture.

In this case the cause of the obstruction

could not have been diagnosed during life, nor could any operation have relieved a stricture so close to the cæcum.

Abscess of the Pancreas and Thrombosis of the Portal Vein.

Abscess of the pancreas is of such rare occurrence that the instructive case recorded by Dr. J. H. Musser, in the April number of the *American Journal of the Medical Sciences*, will receive careful study. Its clinical indications were so meagre that the revelations of the autopsy were surprising; and when the extent of the disease and alteration of structure are considered, it must be regarded as remarkable that the abscess could have existed with so little discomfort to the patient. The pain, the gastric disturbance, and the fever frequent in abscess in this situation, were absent entirely. Emaciation, constipation, a tumor, and pressure symptoms were present, it is true; symptoms and signs, however, due to so many causes so much more common than pancreatic disease, that this affection was quite plausibly, therefore, excluded. The latency of the symptoms appears to point to the chronicity of the abscess. The histological appearances of the pancreas, and the sequence of the pus formation, peritoneal adhesions, and thrombosis (from pressure), confirm this view. The rupture of the pancreatic abscess and its limitation to the duodeno-inguinal fossa are believed to be unique.

Unusual Causes of Coughing.

In these words, Dr. Clarence C. Rice concludes a paper in the *Med. Record*, May 1: The "unusual causes of coughing," then, are two: First, *hypertrophied glossal papillæ, overlapping an epiglottis which is bent far forward, but otherwise normal;* and second, *a congenitally asymmetrical epiglottis, which has been made still longer by inflammation, caused by constant friction with the tongue.* Abnormal conditions of the tongue and ulcerations of the epiglottis are mentioned in text-books as sources of irritation and causes of cough, but this relation between the tongue and the epiglottis has not been specially recognized as a strong cough-producing factor. I believe it is frequently so. I consider the recognition of this lesion to be of great importance to the physician; for it explains the etiology of many coughs the causes of which have not hitherto been accurately determined. Since my attention was first called to this lesion, I have seen many cases in which it existed, and in which it could be demonstrated beyond a doubt that it was the sole cause of cough.

Replacement of Tendon.

The *Med. Record* says that Dr. Assaki states that it is possible to replace a portion of a tendon an inch or more in length by a similar piece taken from another animal. When the operation is performed under antiseptic precautions union takes place in about a week, without any impairment of function of the tendon, which glides in its sheath normally, unrestricted by adhesions. He has made successful transplantations, not only from one animal to another of the same species, but also from dogs to rabbits, and the reverse, and even from birds to mammals. Subsequent examination of the animals operated upon showed complete union of the sutured tendons, the only trace of the operation being an increased vascularization of the tendon sheath. The author argues that the operation ought to be equally successful in the human subject. In his experiments the transplanted portions were united to the divided tendons by catgut sutures, and strict antisepsis was maintained.

Treatment of Cerebral Syphilis.

In the *N. Y. Med. Jour.*, May 1, this question is discussed by Dr. Herbert G. Lytle, who concludes that the treatment of crebral syphilis is, of course, by mercury and iodide of potassium. The former is curative, the latter palliative. It is strange to see in an English work on syphilis, published in 1884, the statement that iodide of potassium, in some cases, must be given in large doses, ʒj to ʒij in twenty-four hours; but that, as a rule, it is better to begin with about seven grains three times a day. In cerebral syphilis it is best to commence with thirty grains, t. i. d., and rapidly increase the dose until you get its physiological effect or the symptoms disappear. The hygienic management is important. The diet should be plain and nutritious. The patient should avoid bodily and mental exertion or excitement. He should not, as a rule, take alcoholic stimulants. Special symptoms must be met by appropriate treatment.

The Treatment of Scaling and Crusting Syphilides.

The *New York Med. Jour.* tells us that Rollet and Chambard (*Union Médicale*) remove the scales or crusts by means of vapor

douches, poultices, or wrapping with sheet-rubber. They prescribe a tepid bath, and paint the raw surfaces with tincture of iodine, or cauterize them lightly with a stick of nitrate of silver; finally, they apply an occlusive dressing of overlapping strips of *emplâtra de Vigo*. In cases of impetigo, rupia, and deep ecthyma, this mode of treatment allays the pain and irritation, and rapidly transforms the specific ulcers into simple ulcers. Where there is a tendency to destructive ulceration, before applying the strips of plaster the surface is cauterized rather energetically with the stick of nitrate of silver, with chloride of gold, or, if necessary, with the actual cautery.

Suicide by Butting the Head against a Stone Wall.

Mr. William Allan reports, in the *Dublin Journal of Medical Science* for March, 1886, a case of a prisoner who, on being informed that his wife had just been arrested, started off at full speed toward a wall some fifty feet away, and dashed the vertex of his head against it. So great was the concussion that the body rebounded three feet from the wall, and the man dropped dead without a struggle. The case was of interest from a medico-legal point of view, as if the man had not been seen by witnesses to commit suicide it might reasonably have been supposed that he had been struck by a keeper, or a fellow-convict.

Œsophagotomy for Foreign Bodies Lodged in the Tube.

The question of the propriety of this operation is ably discussed by Dr. T. M. Markoe in the *N. Y. Med. Jour.* (May 1), who concludes from the premises given that he would deduce the following surgical rule: To attempt the removal of foreign bodies impacted in the œsophagus as soon as proper instruments can be procured, and failing, after a fair and sufficient trial, to proceed at once to the operation of œsophagotomy.

Correspondence.

Human Triplets and Equine Twins.

Eds. Med. and Surg. Reporter:

Dr. J. N. Study's trio of girl babies at one birth, reported in the Med. and Surg. Reporter, April 10, reminds me of a case which came under my observation on the 23d of November last. Mrs. Taylor, aged 38 years, mother of twelve children, gave birth to three girls, first with vertex presenting, the other two breech, within about five minutes of each other; one placenta. Weights at birth 7, 6½, and 4½ pounds respectively. At this date they are doing well, and weigh as follows: 15¼, 14¾, and 12½ pounds. These three added to the other twelve make fifteen in all for Mrs. T. Two of the twelve are twins.

On the same farm, a mare gave birth to twin mule-colts, and a ewe to four lambs. "*Must be in the water.*"

Charles U. Harrison, M. D.

White Oak, Arkansas.

News and Miscellany.

American Medical Association.

On Tuesday, May 4, the American Medical Association commenced its annual session in St. Louis.

Dr. Atwood introduced Dr. Brodie, president. Prayer was offered by Rev. Montgomery Schuyler, D. D.

THE ADDRESS OF WELCOME

was given by Hon. D. R. Francis, Mayor of St. Louis.

Dr. Atwood welcomed the Association on behalf of the medical profession of St. Louis. The ex-presidents were invited to take seats upon the platform, and Drs. N. S. Davis, of Chicago; J. M. Toner, of Washington; T. G. Richardson, of New Orleans, and D. Yandell, of Louisville, were present.

Dr. Atwood then announced the programme for the entire meeting, with entertainments numerous and inviting. He also announced the presentation of

PROTESTS AGAINST DELEGATES

from the following organizations: Philadelphia County Medical Society; Davidson County, Tenn.; the Tri-State Medical Society, the Mississippi Valley Medical Association, the Tennessee State Medical Society. All these were referred to the Judicial Council.

The following gentlemen were elected

MEMBERS BY INVITATION:

Colonel Manfred Johnson, of McHenry, Ill.; Drs. William W. Morrison, of St. Louis; H. J. McKellops, of St. Louis; W. H. Atkinson, of New York.

Dr. William Brodie, of Detroit, Michigan, then delivered

THE PRESIDENT'S ADDRESS,

in which, after referring to the facts that no

epidemic disease had invaded the country during the last year, that a favorable state of health had been given by the members, then made special reference to the inroads made among our ranks by the removal by death of Drs. Bowling, John L. Atlee, and Austin Flint, of whom he gave brief biographical sketches. From this he passed to a sketch of the history of the organization of the Association, beginning with 1846, when it was conceived by Dr. Hayes, of Philadelphia; special reference was made to the influence of the Association on the question of the elevation of the standard of medical education. The influence of the code, as sustained by the Association, was dwelt upon, and the chief interest in this part of the address centred in the statement that the movement in the State of New York against it was due chiefly to financial considerations.

Dr. Brodie then referred by title to the papers which had been read before the Association, and which had made a healthy impression upon the minds of the profession.

He regarded the Association as no pent-up Utica, but as sufficiently broad to meet all the necessities of the profession, through its sections, and, therefore, that additional national associations were unnecessary. He favored the adoption of resolutions sustaining the National Board of Health.

He recommended the abolition of the metric system from the "Transactions" of the Association. He recommended the formation of a Section on Dermatology and Syphilis, also that the secretaries of sections be permanent officers, subject to removal in the wisdom of the section. He spoke of the success of the *Journal*, and directed attention to the by-laws, which make every paper received by the Association its exclusive property, and said that it was improper to give copies to outsiders; but that if medical journals were sufficiently enterprising to employ competent men to take notes from which abstracts were to be made, while the papers were being read, no obstacle should be thrown in the way. Practically, there was no difference between a patented and a proprietary medicine, and whoever lent his name to the support of either should be disciplined in local societies.

With regard to the question of establishing branches, after the manner of the British Medical Association, he recommended that the subject be referred to a committee for report.

CONCERNING THE INTERNATIONAL MEDICAL CONGRESS,

all that remained to be done was for the Association to adopt the report of the Committee, which would soon be made, and thus relieve itself of all further responsibility in the matter.

He entered into a history of the Congress, and closed with an expression of the belief that the general sentiment of the profession was in favor of adopting the report of the Committee, and when adopted that personal feeling should yield to the common good of the profession.

The address was closed by the President returning to the Association his thanks for the honor it had conferred upon him.

Dr. Murphy, of St. Paul, moved that the thanks of the Association be tendered to Dr. Brodie for his address; that it be referred to the Committee on Publication, and that all its recommendations and special points be referred to the appropriate committees. Carried.

THE NOMINATION OF OFFICERS OF SECTIONS.

Dr. Davis spoke of the method of nominating officers which was laid on the table last year. He fulfilled his promise to bring up the subject this year, to change the present order of nominating officers of sections.

Dr. Kinloch, of South Carolina, protested against the attempt to make specialists of all the members. It was all very well in the North and in the Eastern States; but there were many who did not want to be restricted to any particular section, as they would be by the proposal.

Dr. Eugene Smith, of Michigan, opposed the amendment on the ground that it would give asplrants to chairmanship an opportunity of packing meetings with their supporters.

Dr. Murphy thought the proposal was all very well for the Eastern States, but in the West men could not always be specialists. The existing rule worked well; he hoped the motion would not prevail, and he should oppose the amendment.

Dr. Dudley S. Reynolds, of Kentucky, spoke in opposition to the amendment.

A member moved that further action on the whole matter be deferred until after the question of receiving delegates had been settled. Not seconded.

Dr. Staples, of Minnesota, said the sections would only nominate and not elect, so that there would be no use in log-rolling.

Dr. Murdock, of Pennsylvania, supposed it was important that the Association should not be turned into a political organization. They had met to discuss medicine and science, and not wire-pulling.

Dr. W. W. Allport, of Chicago, strongly advocated the adoption of the amendment.

Further discussion *pro* and *con* was participated in by others, and, on the amendment being put again, the President decided by a show of hands that four-fifths were in favor of its adoption.

The Committee on Nominations was then announced: Alabama, Arkansas, Dr. P. O. Hooper; California, Colorado, Dr. J. W. Graham; Connecticut, Dr. W. C. Wile; District of Columbia, Dr. J. W. Bulkley; Dakota Territory, Dr. J. B. Van Velsor; Delaware, Florida, Dr. T. O. Sommers; Georgia, Dr. J. W. Bailey; Illinois, Dr. J. E. Owens; Indiana, Dr. T. B. Harvey; Iowa, Dr. W. Watson; Kansas, Dr. C. V. Mottram; Kentucky, Dr. W. H. Wathen; Louisiana, Dr. Joseph Jones; Maine, Dr. Charles E. Webster; Massachusetts, Dr. E. W. Cushing; Maryland, Dr. G. H. Rohé; Michigan, Dr. H. O. Walker; Mississippi, Dr. P. W. Rowland; Missouri, Dr. G. F. Dudley; Minnesota, Dr. H. H. Kimball; Nebraska, Dr. W. M. Knapp; New Hampshire, New Jersey, Dr. E. L. B. Godfrey; New York, Dr. E. S. F. Arnold; North Carolina, Dr. C. J. O'Hagen; New Mexico, Dr. W. R. Tipton; Ohio, Dr. H. J. Sharp; Oregon, Pennsylvania, Dr. J. C. Lange; Rhode Island, Dr. H. R. Storer.

Dr. Nicholas Senn, of Milwaukee, then delivered

THE ADDRESS OF THE CHAIRMAN OF THE SECTION ON SURGERY AND ANATOMY,

in which he directed special attention to

THE PRESENT STATE OF ABDOMINAL SURGERY

by a condensed account of the advancement which had been made within the last few years in that department. He limited his remarks to the consideration of such injuries and lesions of the abdominal organs as were liable to be presented to physicians and general surgeons, aiming particularly to point out

THE LIMITATIONS OF ABDOMINAL OPERATIONS,

and to draw a distinct line between feasibility and justifiability. The first topic was penetrating wounds of the abdomen. The chairman mentioned the distinctions between punctured and gunshot wounds, and spoke of these as important with reference to diagnosis and treatment.

EXPLORATIVE LAPAROTOMY

had for its objects positive diagnosis, arrest of hemorrhage, restoration of breach of continuity, and removal of extravasations. Dr. Senn prefers the bichloride to carbolic acid, and for uniting divided ends of intestine the Czerny-Lembert suture was the only one which should be used. If any doubt exists concerning the aseptic condition of the peritoneal cavity, a drainage-tube should be inserted. He insisted upon the justifiableness of explorative laparotomy in all doubtful cases.

LAPARO-COLOTOMY

was the next topic, which was followed by that of subcutaneous laceration of intestines. Then came intestinal obstruction. The treatment of this condition by laparotomy was in its infancy, yet sufficient good results had been obtained to stimulate additional efforts in studying its limit of application. The results would improve as soon as physicians recognized the insufficiency of the expectant plan of treatment. Intussusception and entero-stenosis followed, and for internal strangulation the rules given by J. Greig Smith were endorsed. These were followed by enterectomy, rupture of the diaphragm, and

TREATMENT OF PERITONITIS BY ABDOMINAL SECTION AND DRAINAGE.

The last had been most successful in cases where the disease had not become diffused, and where the original cause could be removed. Tubercular peritonitis was considered next, and this was followed by gastrotomy, which was of questionable propriety in cases of malignant disease, but was recommended in all cases of non-malignant stricture. Pylorectomy, duodenostomy, and jejunostomy were the last topics considered.

The general conclusion was that abdominal surgery was a legacy of inestimable value, left to us by McDowell, Gross, and Sims, that it should be cherished and studied, and that our knowledge of it should be carefully cultivated.

Dr. H. F. Campbell, of Georgia, ex-President, was invited to take a seat upon the platform.

Dr. S. C. Gordon, of Portland, Me., then delivered

THE ADDRESS OF THE CHAIRMAN OF THE SECTION ON OBSTETRICS AND DISEASES OF WOMEN,

in which he said that nothing remarkable had been done or discovered in these departments during the last year. He could only emphasize matters which had been alluded to, and perhaps weigh inferences which had been made on topics that had been more or less discussed. With reference to attend-

ing cases of labor after having made an autopsy or while in attendance upon cases of puerperal fever, etc., he believed that the weight of opinion sustained the view that with proper regimen and absolute cleanliness, the daily work of the physician could be safely continued without delay or anxiety. The criminality was in the neglect to take proper precautions, and time might not be an element of safety if these were not observed. Concerning the early signs of pregnancy, he regarded Hegar's test as especially valuable, and one which was applicable early, namely, increase in the anterior curvature of the uterus, with increased elasticity of the uterine wall. For the obstinate vomiting of pregnancy no one measure was of so much value as forcible dilatation of the cervical canal below the internal os. In producing premature labor he recommended the use of the bougie, and when done on account of disproportionate head the eighth month was the most favorable time. He favored the use of a nutritious diet during the parturient period. For ameliorating suffering and shortening the process of labor, anæsthetics and the forceps had done much, and had thus prevented many of the injuries formerly incident to the parturient process. Under the judicious use of the forceps, vesico-vaginal fistula was diminishing in frequency.

The treatment of the placenta in both normal labor and abortion had been written of so satisfactorily by Pajot that nothing need be added. At full term the placenta was best removed by prompt and gentle traction on the cord, and the earlier after the delivery of the child this was effected, the more easily could it be done and the less evils come therefrom. Forcible removal of membranes in abortion was by no means the safer practice. Remove them if it can be done without much trouble or instrumental interference; otherwise carefully tampon the vagina, and less harm would be done than by resorting to forcible means.

In the deparment of gynecology only one theme was introduced, and that was the removal of uterine appendages, included under the three operations known as Battey's, Tait's, and Hegar's. After making some remarks, the chairman spoke particularly of hysteria and its relation to diseases of the uterine appendages. This part of this subject was discussed at much length, and accompanied by the histories of illustrative cases in which cure had been effected by the operation. He had removed the uterine appendages in twenty-five cases, and with only one death. The conclusions reached by the speaker were based upon his study of the subject and the favorable results obtained in these cases.

Dr. A. L. Gihon, of Washington, chairman of the

RUSH MEMORIAL COMMITTEE,

reported that in obedience to the resolutions adopted by the Association at its last annual meeting, the committee had been instituted by the appointment of one member from each of the States, Territories, and national services represented in the Association, and that the Standing Committee thus organized would proceed at once to collect funds for the erection of a statue of Dr. Benjamin Rush, in the city of Washington, by the members of the profession of medicine in the United States. No further time should be lost by the medical profession in completing its enduring testimonial of one who was not only a great physician and teacher of medicine, philosopher, philanthropist, and accomplished writer, but a fearless patriot and founder of the Republic, a signer of the Declaration of Independence, an officer of the army of the Revolution, and one of the authors of the Federal Constitution.

With this announcement the Rush Memorial Committee will at once undertake the work of obtaining subscriptions, which have been limited by resolution of the Association to one dollar from each member of the profession of medicine in the United States, and receiving such voluntary donations as may be made by persons interested in this great undertaking. The secretary of the committee is George H. Rohé, of Baltimore, and the treasurer, J. M. Toner, of Washington, D. C.

The report was accepted and referred to the Committee on Publication.

Dr. I. N. Quimby, of New Jersey, moved to take from the table the resolution introduced at the last annual meeting, providing for a new section, namely, one on medical jurisprudence, which was carried.

A motion for its adoption gave rise to discussion by Dr. Logan, of New Orleans, who thought that the necessity for such a section did not exist, and by Dr. Campbell, of Georgia, who originated the idea of establishing this section.

The resolution was adopted.

The President acknowledged the receipt of a communication from the Texas State Medical Society, extending its congratulations to the Association on its growth and usefulness, which was accepted and ordered entered upon the minutes.

HYSTERIA AND ITS RELATIONS TO DISEASE OF THE UTERINE APPENDAGES,

was the title of the address by Dr. S. C.

Gordon, of Maine, chairman of the Section in Obstetrics and Diseases of Women, and dealt principaily with the subject of Battey's operation. It consisted largely of extracts from Dr. Hammond's book on nervous diseases, and the recital of the results of the operation for removal of the uterine appendages.

THE REPORT OF THE SPECIAL COMMITTEE ON CREMATION

was read by Dr. J. M. Keller, of Arkansas. The committee moved to amend the original resolution so as to read:

"*Resolved*, That cremation or incineration of the dead has become a sanitary necessity in populous cities, and that this association advises its adoption."

The amendment was adopted by a vote of 159 to 106.

THE ADDRESS IN STATE MEDICINE

was read by the chairman, Dr. John H. Rauch, of Illinois, who defined State medicine as the office of the sanitarian promoted by the State. He predicted its perfection, and its extinction when every member of the community should have become by education a sanitarian, making the interference of the State unnecessary. He referred to the regulating of medical practice by the State, which was now done by thirty-three states add territories. He stated that there were one hundred and twenty medical colleges in the United States in which the facilities for teaching and the competency of the instructors would compare favorably with those of similar institutions in any other part of the world. The number of physicians in the United States was stated at 106,947. He recommended that the association place itself on record as in favor of an extension of the term of study to four years, and of the period of attendance of lectures to three full terms, with ample hospital and clinical experience, as among the requirements for graduation. He urged the appointment by the association of a standing committee on medical legislation, to frame a law for regulating the practice of medicine, which law, when it had been indorsed by the association, should be the standard to which all existing laws must conform. State and municipal boards had done effective work in their respective spheres, but the subject of the registration of vital statistics was still in an unsatisfactory state, yet the death-rate for 1885 compared favorably with that of previous years. He said that the National Board of Health continued under the act of March 3, 1879, and that a re-enactment of the law of June 2, 1879, would restore it at once to activity. He commended the work done by the American Public Health Association, which was of more than usual practical value. The Sanitary Council of the Mississippi Valley, although it had not been called upon for action, was still organized and ready for an emergency.

Dr. J. T. Whittaker, of Cincinnati, then delivered the

ADDRESS OF THE CHAIRMAN OF THE SECTION ON PRACTICE OF MEDICINE.

There are three planes in the history of medicine: First, the study of the symptoms or appearance of disease; second, the observation of the effects or lesions of disease; third, investigation into the cause of disease. The etiology of acute infections is comprised under the single term bacteriology, for it has now been demonstrated that pathogenic micro-organisms do exist beyond dispute in distinct and definite entity. The speaker then considered the theory of spontaneous generation, the claims of convertibility of all germs, the question of mutability or immutability, the deviations that do occur, the doctrine that the germ, not the form, is essential, the morphology of bacteria, the destruction of bacteria, the formation of zoöglea, the subject of pure culture-soils, the necessities with reference to temperature and the need of oxygen, the fecundity of micro-organisms, the topic of spores and saprophytes, the mode of invasion and dissemination, the effects upon the tissues, their presence in neoplasms, in giant cells, in the blood. The question of immunity was studied, and also the manner in which micro-organisms produce the phenomena of disease. The address concluded with a brief reference to the subject of ptomaines.

(*To be continued.*)

Sanitary Inspectors at Foreign Consulates.

From the Washington correspondent of the *N. Y. Med. Jour.* we learn that "upon recommendation of the Surgeon-General of the Marine Hospital Service, the Acting Secretary of the Treasury has requested the Department of State to appoint sanitary inspectors at the United States consulates at Genoa, Naples, Marseilles, and Venice, with instructions to give prompt information of the appearance of cholera in any of the consular districts named, and to report the departure of emigrants and merchandise for the United States from infected districts. The disease has not appeared in any of the ports named, but is reported to exist in vil-

lages in the same consular districts. This is in pursuance of the plan so successfully carried out for the past few years, and in view of the recent cases at Brindisi, and the alleged cases at Venice, is a timely and necessary precaution. There is said to be some higgling in Congress about the authority of the United States to have these sanitary *attachés* to the consulates; but it seems there has never been any question about the employment of military or naval *attachés*, or of the payment of their salaries while so engaged, consequently such obstructionists must have some more valid reason than lack of precedent. The same argument was used to defeat the proposition of Surgeon-General Hamilton to make an inspection of the foreign quarantines. He proposed to make a thorough inspection, obtain photographs and maps, and publish in a report, for the general information of health officers, the result of his personal observations. The cry of no precedent was immediately raised—a cry which, thus far, has not availed to prevent appropriations for sending commissioners to the tops of foreign mountains and islands beyond the sea to take triangulations or photographs of eclipses, transits of Venus, or unusual sun-spots. Thus it is apparent that abstract science has more charms to woo our Solons than practical science."

Cremation.

Dr. Wm. Le Moyne Wills thus concludes a paper in the *Southern California Practitioner:*

"I have stood," says an eye-witness, "before the threshold of the crematory with a fluttering heart, and trembled at the thought of using fire beside the form of one I loved. But when, in obedience to his own dying request, I saw the door of the incinerator taken down, its rosy light shine forth, and his peaceful form, enrobed in white, laid there at rest, amid a loveliness that was simply fascinating to the eye, and without a glimpse of flames, or fire, or coals, or smoke, I said, and say so still, 'This method, beyond all others I have seen, is the most pleasing to the senses, and most grateful to the memory.' And as I turned away from the incinerator, where we had left the body of our friend, it was pleasant to think of him still resting in its rosy light, enveloped by what seemed to us as floods of purity." When all was over, nothing remained but a few fragments of calcined bones and delicate white ashes and dust, perfectly pure and odorless.

This mode of disposing of the cast-off body, absolutely innocuous to the living, whose claims should be paramount, seems a more fitting destiny than that it should remain for years and years a mass of loathsome and death-bearing putrefaction. It is a question of custom and association which the intelligence of the nineteenth century should not hesitate to change, for sufficient reasons.

The medical profession has led the way in this reform; among others the Nestor of surgery, Samuel D. Gross, testified to his approval of this method by having his body cremated. Let the example of these great and fearless advocates of reform be emulated.

A Nursery for Scrofulous and Rhachitic Children.

Mr. Rindge, of California, has offered to give Lowell Island, in Salem Harbor, to one of the charities of Boston, as a summer home for scrofulous and rhachitic children. and, in addition, he has guaranteed $1,000 annually for three years toward its support. If at the end of that time the situation is found unsanitary, the property, which is valued at about $50,000, can be sold and the proceeds used for a similar institution elsewhere. Recently a meeting of the staff of the Boston Dispensary was called, to consider the subject from a medical standpoint, and, as it seemed to be the unanimous opinion that such an institution was desirable, those interested called a second meeting, Monday, April 26, to determine how the nursery organization should be effected. As the trustees of the hospitals of Boston, Lynn, Salem, Lowell, and Worcester had not had time to consider the matter, the meeting adjourned to meet at the call of the chairman.

How the Late Dr. Nebinger Bequeathed His Valuable Estate.

The late Dr. Andrew Nebinger, of the Board of Education, left an estate valued at $300,000, of which amount $200,000 is in personal effects. By his will, dated June 30, 1880, and admitted to probate recently in the office of the Register of Wills, $300 goes to the Southwark Soup Society, $1,000 to St. Joseph's Orphan Asylum, Seventh and Spruce streets; $1,000 to St. John's Orphan Asylum, Forty-ninth and Westminster avenue; $1,000 to the R. C. Church of the Sacred Heart, Moyamensing avenue below Reed street; $5,000 to the Sisters of the Order of St. Francis, to be expended in the erection of a hospital on the lot bounded by

Tasker, McKean, and Broad streets and Nebinger avenue.

One-fourth of the residue of the estate is left in trust for the benefit of his sister, Charlotte C. Shaeffer, and at her decease one-half of this trust goes to the Sisters of St. Francis, for the hospital above mentioned.

In the event of the decease of his nephew, Andrew N. Shaeffer, without having issue, the remaining half of the one-fourth part is bequeathed to the Sisters of the Order of St. Francis, to be used in the erection of the hospital. Another one-fourth part is left in trust for the benefit of his sister, Mary A. McMinn, and upon her decease and that of her husband, James B. McMinn, the executors are directed to pay $2,000 out of the principal to St. Joseph's Orphan Asylum, $2,000 to St. John's Orphan Asylum, $2,000 to the House of the Good Shepherd, $2,000 to the Society of St. Vincent de Paul, and the residue to the Order of the Sisters of St. Francis, to be expended in the construction of the hospital building referred to.

The Good Effect of a Disgusting Custom.

A southern secular paper is authority for the following statement regarding the fattening effect of chewing-gum: "Twenty years ago the rule was the Southern women were thin and delicate; it is not the rule now. Southern women are not physically equalled in all North America. Any physician who is as well informed as he ought to be, will tell you that this is true. This change is due to the habit of chewing gum. You may smile, you may even laugh if you please, but I am telling you a plain fact. As to Southern men, they are as thin and gaunt as they ever were, and so they will remain until they cease to chew tobacco and begin to chew gum."

A Healthy City.

Speaking of Goulburn, in New South Wales, a recent English visitor, Dr. J. E. Taylor says: "It is a picturesque and clean town, with wide streets and fine buildings, surrounded by a breezy, open country on one side, and a bold, craggy ridge, half forest-clad, on the other." He then proceeds to state that "Goulburn is said to be so healthy that the doctors rely on the natural increase of population for a living! People are neither in a hurry to be sick nor to die."

Two Senators with but a Leg Each.

Senator Butler and Senator Hampton, of South Carolina, have but two sound legs between them. Neither of them uses crutches, and each wears a cork leg with such skill that the ordinary beholder would scarcely believe that they are thus afflicted. Hampton lost his leg since the war in an accident; Butler left his leg at Brandy Station twenty-four years ago. Upon the anniversary of the battle, which happened only a few days ago, Butler took a trip to the place where he was shot, and where, standing by his side, a brother of Hampton was killed.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDED MAY 1, 1886.

Magruder, G. M., assistant surgeon. Appointed an assistant surgeon, April 24, 1886. Assigned to temporary duty at Norfolk, Virginia, April 26, 1886.

The Congressional Corn Doctor.

The attendants at the congressional bath-rooms are paid out of the treasury, of course. Then to cap it all, a chiropodist, who is on duty, takes care of the pedal extremities of such members as happen to be afflicted with corns, bunions, and the like.

Personal.

Dr. D. D. Richardson, late Physician-in-chief Insane Department Philadelphia Hospital, has located at No. 3204 Chestnut street.

Items.

—Dr. Levick will soon go to the Adirondacks.

—Dr. Philip Leidy, physician-in-chief at the Almshouse, drives a fast bay, which is the envy of lovers of horseflesh.

—A Sanitary Convention will be held at Kalamazoo, Mich., under the auspices of the State Board of Health, on the 1st and 2d of June.

—It is understood that Dr. T. Hollingsworth Andrews has been offered the position of demonstrator of anatomy in Jefferson Medical College.

—The *Scientific American* says oil stains may be removed from paper by applying pipe-clay powdered and mixed with water to the thickness of cream; leave on for four hours.

—There are nine physicians in the House of Representatives, according to the *Weekly Medical Review*, which journal at the same time hopes from them a benign influence on legislation.

—Mr. Andrew Carnegie has generously given $5,000 to the Western Pennsylvania Institution for the Deaf and Dumb, at Edgewood, as a fund the interest of which is to be expended for the increase of the library of the institution.

—In Paris the consumption of fish and other articles of the *maigre* diet in passion week is something enormous: 55 tons of salt cod, 20 tons of pickled herrings, 3 tons of skate, 4 tons of shad, 300 pounds of salmon, with vast quantities of eggs and butter.

—It is announced that Dr. J. S. Billings, U. S. A., has been selected to deliver the Address in Medicine before the next meeting of the British Medical Association, in place of the late Professor Austin Flint. The well-known ability of Dr. Billings, and his familiarity with general medical literature, makes the selection one eminently proper.

—In the *Lyon Médical* and *Journal de Médicine* for March 27, Aubert states that headache and coryza resulting from full doses of iodide of potassium can be prevented by using belladonna. In one instance, in which five grammes of the iodide were administered daily, six grammes of extract of belladonna were also given. A few days later the belladonna was discontinued, and iodism did not return.

—It seems that the little toy balloons or India-rubber bladders which children inflate with the breath may be readily reversed by inspiration and even drawn into the air-passages. In two instances recently death has occurred by suffocation, a balloon of the sort being drawn into the opening of the glottis. This is a matter of danger which ought to be recognized. Parents and nurses should be on their guard.

—Sir Henry Thompson can truly be styled a versatile man. As a physician he attained eminence many years ago, specially distinguishing himself in the field of urethral surgery. He is also well known as an artist, having frequently been an exhibitor at the Royal Academy. He is not unknown as a writer and speaker, having on several occasions championed the cause of temperance reform. He is now busy with a new novel, and bids fair to attain equal renown in the field of romance.

—The Paris correspondent of the *British Medical Journal* refers to the treatment of neuralgia by means of a spray of methyl chloride. Dr. Peyronnet makes this the subject of a doctoral thesis, and states that his own results, and those of Waller, Schultze, Abadie, Debove, and others, show that the methyl chloride spray is most efficacious in neuralgia of the trigeminal nerves (sciatica). The effect is instantaneous, and is due to "congelation of the peripheral expansions of the branches of the nerve."

—The *Southern California Practitioner* says: "We know a physician who, soon after establishing himself in Los Angeles, was very much elated upon seeing an elegant coach stop at his door. A richly dressed lady alighted and rang the doctor's bell. She was most cordially received, but soon sent a cold chill through our medical friend by saying, 'Doctor, my dog Fido is suffering dreadfully with the earache.' The newly arrived Æsculapius made the best of the embarrassing situation, carefully examined the dog's ear, prescribed, and charged the lady ten dollars. The other party then had the chill.

—The Kansas State Board of Health has issued its first annual report, covering the period from its organization, in April, 1885, to the close of that year. Besides a great deal of interesting matter, largely of a statistical nature, the volume contains a number of short practical papers on topics connected with sanitation, contributed by Dr. G. H. T. Johnson, of Atchison, the President of the Board; Dr. D. Surber, of Perry; Dr. W. L. Schenck, of Osage City; Dr. J. Milton Welch, of La Cygne; Colonel William Tweedale, of Topeka; and Dr. J. C. McClintock, President of the Topeka Board of Health.

QUERIES AND REPLIES.

Diagnosis and Treatment Wanted.

Eds. Med. and Surg. Reporter:

Gentlemen: I wish to submit the following case to your "Queries and Reply" column, to see if I can get any light as to diagnosis and treatment:

Patient, male, age 47, of previously good health, excepting that he had scurvy in the army, from which he lost *all* of his teeth, and has not had artificial teeth on account of the unevenness of his gums. Was taken between six and seven months ago with severe headache and ringing in the ears; pain is sometimes across the forehead, but usually runs from the ears backwards, and down back of the neck to shoulders. On getting up or down, or making any exertion, head aches worse, limbs jerk, the eyes roll upwards, and he becomes unconscious for a few seconds. Face rather flushed at all times, tongue red, slightly fissured and seldom coated. Pulse 65 to 70, temperature about normal, bowels costive, appetite usually very fair, but food sometimes passes partially digested. When I first saw him, six weeks ago, headache had been constantly severe for five months. Cathartics, tonics, pepsin, with morphia and bromides, have made the pain almost entirely easy at times, but it is yet often severe. Has had no nausea or vomiting. Conjunctivæ injected.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful Home.

EMPHYSEMA ARRESTING TUBERCULOSIS.*

BY J. M. DA COSTA, M. D.,

Professor of Theory and Practice of Medicine, Jefferson Medical College.

The patient is a woman aged 45, who brings a history of long-standing ill health. She has been exposed to damp houses, has had malarial fever, and for some time past has been suffering from dyspnœa. She was once before in the hospital with symptoms much the same, but in addition there was evidence of lung consolidation, supposed to be tubercular.

She left the hospital in '83, remaining for a time in fair health. She says the cough entirely disappeared. While in the hospital she had some spitting of blood, which symptom has recurred twice since that time, and she has lost considerable flesh.

At the time of her admission she had been ill four weeks, and presented, with decided cough, ralés through both lungs, and slight rise of temperature, which has, since her treatment here, subsided. The urine is normal.

As she appears this morning, her tongue is normal, her respirations 30 per minute; Pulse accelerated, (108,) and it has been continually as high, sometimes varying from 108 to 116 in twenty-four hours. She has no abdominal symptoms. It now remains to determine what significance this cough has. There is considerable expectoration; the right lung is clear on percussion, with extreme resonance posteriorly, especially over the lower part of right lung; the resonance is of higher pitch on the right than on the left side, and only very slightly increased upon deep breathing.

The physical signs are coarse ralés under the right clavicle, which mask the breath-sounds, but where we can distinguish the breath-sounds they are distinctly bronchial low down, while above they are feeble but *not* bronchial.

Left side: respiration is harsh, with moist ralés, that mask the breath-sounds.

What do these sounds indicate?

1. Bronchial catarrh.
2. Consolidation at right apex.
3. Extreme resonance, with harsh breath-sounds, demonstrate emphysema of lower part of both lungs.

The history and signs point to bronchial catarrh of recent origin—acute, without doubt. But this emphysema; is this a bronchial catarrh which often co-exists with emphysema?

Mark the shape of the chest. How long has she had this emphysema? I believe for years. What relation has it to the consolidation at the right apex? Both are chronic, for our old hospital notes show it.

There is no evidence of hereditary phthisis, though at the time of her first admission to hospital, the signs were of phthisis.

The question now arises: How is it that she had this long interval of comparatively good health? This is the very interesting point.

Emphysema has arrested the development of consolidation of the lungs, which bore all the signs of tuberculosis. Indeed, so true is it that a condition of dilated air-cells is thought

* Abstract of lecture delivered in the Pennsylvania Hospital.

favorable to tuberculosis, that we formerly tried to devise means to bring about emphysema, hoping thereby to arrest the progress of this disease; the reasons are not yet fully explained.

The patient's treatment, which was commenced February 25, has been—

℞. Ammon. chlor., gr. x.
Tr. opii deod., gtt. vj.
Syr. prun. virg., ʒj.
M. S.—Dose every hour—

since which time the cough and expectoration are lessened. She may now have less opium, and as soon as the acute condition of the catarrh is better we will administer cod-liver oil and iodide of potassium 10 grs. three times daily, which will relieve the dyspnœa and improve her general condition. From every point of view, this case is one of considerable interest.

CATARRHAL FEVER SIMULATING TYPHOID.

Here is a woman, aged 21 years, who tells us that her mother and one sister died of consumption. She has one child, (two years old,) who seems healthy. Patient was well till her thirteenth year, when the menses were established. She soon lost much blood, and her general health suffered, but after marriage this improved, and she was in comparatively fair health till three weeks ago, when she complained of chilliness, followed by nausea, vomiting, and complete anorexia.

She endeavored to relieve obstinate constipation by the use of salts, which induced excessive purging (as in typhoid fever), and there was a continued rise of temperature, especially in the afternoon. At present the bowels are constipated, the tongue coated and red at the tip and edges. Countenance dull, pulse weak, temperature 101⅕°. Urine is 1016 sp. gr. and normal. Skin is dry.

The temperature chart shows on the day of admission a temperature of 101⅕°; the following day it fell to 100°, next day to 99°, then to 98°, and one day later shoots up to 100°, then suddenly to 98° again. This extreme irregularity is *unlike* typhoid. The mind was dull and heavy for the first few days, but is now better. The tongue, which was then dry, is moist. There is no eruption, though it has been sought for repeatedly. At first there was some tenderness of the bowels, but this has also disappeared. There is no heart lesion.

What is the diagnosis? This woman has had a catarrhal fever, simulating typhoid fever, and aggravated by colds. Such fevers are calculated to mislead the practitioner and cause errors in diagnosis. Epidemics of such fever sometimes occur; in fact, such an epidemic exists in the city at the present time, under the false name of typhoid fever.

It would seem that the intestinal irritation was the *main* misleading point. But in beginning typhoid fever, we do not have nausea, vomiting, etc., causing the patient to seek relief. Temperature is not irregular, as in this case. I do not hesitate to say that this is a case of protracted catarrhal fever. I have known cases to last for weeks, but with judicious treatment they always end in recovery.

The diet is of great importance, light, easily digested food, (chiefly liquid,) milk, beef tea, etc., because of the intestinal irritation. Watch the secretions, and endeavor to keep them in normal condition.

We gave this patient an occasional laxative, and as she was very restless at night morphia, and as the tongue became dry some aromatic acid and quinine. For the dry skin we ordered sponging, as there was slight fever. We also gave her

℞. Phos. ac. dil., ℥j.
Tinct. cinchonæ comp., ℥ij.
Simple elixir, ʒj.
M. S.—One drachm before meals.

The best laxative would be castor oil, but this is so difficult to take, that we have substituted confection of senna.

COMMUNICATIONS.

CLINICAL DIETETICS.

BY T. C. SMITH, M. D.,

Of Aurora, Ind.

The following case will illustrate many that are met with in practice. This was the case of a female; but the male often presents the same symptoms, so far as dietetic influences are involved on the general system:

Mrs. X., æt. 25, mother; one child, æt. 26 months. She is of French-American extraction, has dark hair and eyes and florid face. Her height is five feet four inches; weight, 140 pounds; very muscular, and carries considerable adipose tissue. She presented the following history: About thirteen months after birth of her child she supposed she was pregnant, but at the second menstrual period the discharge appeared. She states that it was then very free, continued far beyond the usual period, and became very offensive after the first two days. This condition has been repeated three times since that, and she is now in the second week of the fourth men-

struation of this character. To diagnose this condition now and dispose of this feature of the case may be most convenient. It seems clear to my mind that this lady had four times become pregnant, and that this caused the interruption of the menses. Their return, accompanied by the above-named symptoms, indicates the discharge of a blighted ovum. That she did not in any way, by intention, produce this blight of the ovum and return of the menses, I am fully persuaded, as that is not according to her wish; but whether the cause lay in the general extra plethora of blood and oversupply of nutrient material from overfeeding, we leave the reader to judge for himself. She did not come to complain of this condition of her menses, but of other systemic derangements.

She is troubled much of the time with a heavy supra-orbital pain. Some disturbance of vision at times, as the entangling of letters before her eyes; has a bad taste in the mouth much of the time, especially of a morning on rising; tongue is covered with a firm yellow coating, is thick, and disposed to be indented by the teeth. She has a strong, craving appetite, eats regularly, and does not piece between meals; complains that her food does not digest well; has constant bloated sensation in the stomach; very frequent eructations that demonstrate an acid fermentation rather than normal digestion of the food eaten; does not often vomit; has a dull pain in the liver much of the time; bowels are greatly constipated—do not move for three or four days without the use of some cathartic medicine; has been using some patent pills for this purpose; feels better after operation. The urine has been troubling her for months; it is scalding, sometimes very high-colored and scant; often free, but scalding; attributes this to disease of the kidneys; says "when the urine stands awhile in the vessel it leaves a thick pink stain and sediment on the bottom of the vessel; sometimes the urine is almost ropy, it is so thick."

To the question, "Do you feel depressed much of the time, and sometimes very cross toward everybody and everything?" she replied, "I do feel very greatly depressed, and cross too."

"What food do you crave most, and of what do you most freely partake?"

"O, I eat everything that is good if I can get it. I use meat freely, eggs, fried victuals, butter, cakes, molasses, and usually eat all I want, and that is considerable. I do my own housework, and that keeps me going most of the time."

She further stated that about an hour after eating she was usually greatly annoyed with indigestion, eructations of sour gas, has supra-orbital pain, and feeling of great depression, often very cross. This woman is naturally cheerful and kind.

Now this is not a remarkable case by any means, and its type is met with almost daily in the office of every busy physician. What is the trouble? Is it simply one of dyspepsia with constipation? Do these chylopoetic derangements have their origin in a strong sympathy with the uterus? The specialist might think so, and be led to ply a course of treatment directed to that organ, innocent though we deem it to be of all this offence. That there are dyspeptic symptoms is true. Shall we therefore ply the case with pepsin, peptonoids, digestive tonics, and stimulants? To do so is only to give the patient temporary relief, and ultimately render the condition of the stomach worse. It is too much like whipping the over-tired horse, instead of resting him. True, he works better for a while, but it renders his plight only the worse at the last. But then if we turn to the liver, we find it also growling at its overburden, and making its overworked state known by the dull pain and its engorged condition. Shall we, therefore, keep giving soda and cholagogue cathartics to spur it to increased effort? This will relieve it for a while, just as the digestive agents and stimulants relieve the indigestion in the stomach. But this relief is only transient.

If we turn to the kidneys, we find that they too are drawn upon to the utmost of their capacity for labor. They manifest this by the dull pain across the loins, by the high-colored and strong-smelling urine, but more by the character of the sediment which the urine casts down when allowed to cool and stand awhile. This clearly indicates that the overworked liver is trying to find relief by throwing a part of its excess of labor on the kidneys. These in their turn are doing their utmost to relieve the system by the elimination of their usual proportion of the ordinary waste material, and of the excess of unassimilated material that the liver could not prepare for a higher step in the process of assimilation and tissue building.

We, in short, have a case in hand of a naturally stout, robust, healthy, good-natured and industrious woman, who has for months and very probably for years overfed herself. Not only so, but she has crowded on a very great excess of nitrogenous food. The results have been seen in the production of

some marked dyspeptic manifestations of a grave character; by engorgement of the liver, by the overworked kidneys, by the supra-orbital pain, crossness and depression of feelings, and by relative inactivity of the bowels, as shown in constipation.

Now, what course of treatment shall we pursue? Four channels of relief are open: *a*, digestive stimulants; *b*, free catharsis; *c*, increase of physical labor; *d*, regulation of diet. Which route shall we take? Which is the most practical? If we look to immediate relief, without regard to permanency of results, the second is the best. To follow the first channel will result in worse than failure at the last, though it may slowly bring relief at first; for the over-stimulated stomach will flag at the last, in spite of stimulants, and be left weaker than when the treatment was begun, and far less able to recuperate. The third channel—more work—in this case cannot be applied. In some others, where lazy indolence is habitual, it will be just the line needed and the most practical, provided you can get the lazy lout to think so. Albeit, the physician who advises this course in some of these lazy cases had better collect his bill before the lazy lout departs from his presence. But if we turn to the last channel of relief, especially if we precede it by the second, *i. e.*, catharsis—salines are best—we will hit the nail fairly on the head. An excellent threshing machine may be fed too rapidly and choked down. The remedy is to clear it of the excess of straw, and then feed less and with regularity. That is just what is needed in these cases. Clear the system of the excess of waste tissue and of unassimilated material that are floating in the blood and stowed away in the cells of the different tissues, and at once the patient feels relieved, digestion improves, mental hebetude is gone, the liver clears itself of its overburden, and the kidneys give normal urine again, because their overwork has been taken off down to their healthy amount.

If now we let the patient eat to gluttony again, the same state of things is soon reestablished. But, if now we regulate the quality of the diet, and govern, to a fair degree, the quantity eaten, we shall keep our patient in health with the use of but little or no medicine. A placebo may be needed to satisfy the mind, but often not otherwise.

What should such a patient eat? It is better to ask, what such a patient avoid eating? If we can list the latter, the former will be easily comprehended.

All, or nearly all, nitrogenous articles of diet should be eschewed, for it is this class of articles that throw the greatest weight of work on the stomach and liver, and lastly on the kidneys. When nitrogenous diet is indulged in by such a patient with freedom, he must eat very little of the non-nitrogenous class of food at that same meal. The two conflict sufficiently in the processes of digestion and assimilation to make it quite difficult for an impaired stomach and liver to carry the different steps to a full completion. To stop short of it is to bring upon the patient a return of the old symptoms with all their fulness, because it leaves the liver overloaded, the blood overcharged with waste and unassimilated material, and the kidneys soon choke up by reason of the extra demands made on their eliminative powers.

In the foregoing case, I ordered a free cathartic of salts, and directed that all manner of meats, eggs, butter, fatty foods, and rich pastry, must be scrupulously avoided. Nuts must also be eschewed. She must eat regularly, and live on vegetable foods, fruits and salt fish. Milk might be used freely if not taken with more than a very light meal. Buttermilk was commended. She must exercise freely. If her housework was not sufficient she must find other means of exercise. The constipation was to be overcome by the use of the unbolted flour made into bread, pancakes, or mush, by the fruits, and by the prompt answer of all the calls of nature. As to medicine, she took a weak solution of hydrochloric acid for a few days after each meal, and nothing more. She was advised to drink very freely and often of soft water; to drink, indeed, far in excess of what she felt the need of. This was to assist in the elimination of the waste and unassimilated material of the system. It also aids in the relief of constipation. Most persons could find the very best watering place for health right at the nearest cistern of pure water, if they would do so, instead of visiting expensive watering places. It is often more needful to flood the system with water, as a means of elimination, than we are wont to believe. The course indicated above will relieve most of this class of cases completely, and more permanently than will the free use of medicines.

As a rule, we in this country use too much nitrogenous food, *i. e.*, too much animal food, etc. The proportion of nitrogen demanded by the system is pretty large, and is not supplied as largely from the atmosphere as was formerly supposed; but the supply comes chiefly from a nitrogenous diet. Still, it is easy to overstock the system, easy to thus throw too

much work on the digestive, assimilative, and excretory organs, and thus produce a serious state of ill health. In fact, one may, by overfeeding, fill his blood, as it goes flying through its channels, with material that cannot be assimilated and made into tissue, and cannot be eliminated with sufficient rapidity to relieve the system. It therefore can do no other thing than decay while thus floating in the circulation and glands of the system. This makes it poisonous. It becomes a disease-producing power. There is animal matter rotting in the blood of the system. The subject has a storm of cephalalgia, of bilious colic, or it may be even of renal colic, of great dyspeptic depression; or it may develop, with a little malarial complication, a full-blown bilious fever, or a periodic neuralgia of no pleasant proportions.

On this subject Pavy wrote (Pavy on "Food and Dietetics," p. 505, ed. 1874,) in this strain, "The effect of a highly nitrogenized diet—and it is animal food which is characterized by richness of nitrogenous matter—is to throw upon the system a large amount of eliminative work. The nitrogenous matter in excess of that which is directly applied to the growth and renovation of the structures of the body undergoes a process of retrograde metamorphosis, and is resolved in part into certain useless nitrogenous products which have to be cast out by the agency of the glandular organs with which we are provided. Now, as long as free exercise is taken, and the circulation is kept in an active state, favorable circumstances exist for the absorption of oxygen and the proper occurrence of metamorphosis and elimination. Thus circumstanced, a diet into which animal food enters largely—a diet, that is, rich in nitrogenous matter—is borne with ease, and, indeed, may be said to conduce to increased tissue formation and the development of a high state of bodily health and strength. Conjoined with sendentary habits, however, a different result is observed. The sluggish circulation which such habits tend to occasion naturally entails defective oxygenation. This, in its turn, leads to imperfect metamorphosis, and the two together conspire to induce deficient eliminative action. Thus the system becomes more or less clogged with effete products, which act perniciously in various ways upon the body. For instance, there is reason to believe that they may sometimes in a direct manner constitute the source of gouty deposits in the joints. They undoubtedly give rise to the presence of a preternatural amount of solid matter in the urine, manifesting a proneness to become deposited under the form of sand, gravel, or stone."

I have twice, recently, been called to see, in counsel with Dr. L. Louden, of Wilmington, Ind., a young man suffering from nephritic colic of a very severe grade. This young man is a hearty eater, as reported to me, using freely of nitrogenous food, and is not at all sparing of non-nitrogenous diet also. He works little or none. The result is that his urine is loaded with waste nitrogenous products. These gather in the kidney in a sufficiently concentrated state to form a concretion, which, when it is dislodged and starts down the ureter, causes the young gentleman to suffer dearly for his idleness and the too free, pleasant indulgence of his palate. The remedy here is clear. More work or less nitrogenous food, or both, would be better than either one alone. Such cases are not uncommon.

But Pavy continues (*loc. cit.*): "They likewise disturb the action of the liver, producing a disposition to the occurrence of bilious derangements. Besides these effects, evidence is not wanting to show that through their influence the other functions of life are, to a greater or less extent, interfered with. To obviate, therefore, the production of these disordered actions, those who lead an inactive life should not allow their diet to contain a preponderance of nitrogenous food."

Our knowledge of the demands of the system in the way of food has now reached a point where we ought to teach ourselves and our patients what to eat. This matter is of too much importance to allow mere fancy or the mere pleasing of the palate to govern us in our eating and in our advice to those coming under our care. It is often better to diet a patient properly and wisely than to stuff him with drugs.

CONCURRENCE OF MEASLES AND TYPHOID FEVER.

BY DANIEL B. D. BEAVER, M. D.,

Of Reading, Pa.

Willie W., æt. 6, recovered from an attack of measles on the first day of May, 1880. Two days later his brother, æt. 4, went to bed sick, after having complained several days of loss of appetite, lassitude, and peevishness. There was elevation of temperature, dry skin, thirst, headache, anorexia, and nausea and vomiting whenever any food was taken. These symptoms gradually increased in intensity, and were taken as constituting the first stage of measles, until the

fourth day, when the absence of the catarrh of that disease cast a doubt upon the diagnosis. On the fifth day the temperature was measured and found to be 103.4° between 11 and 12 a. m. Now a dry, hacking cough appeared, but no other signs of catarrh —no lachrymation nor sneezing, and no congestion of the pharynx or palate. The bowels up to this time were natural. The pulse varied from 110 to 125. The headache had now almost ceased, and the patient's mental condition had changed from restlessness and irritability to that quiet indifference which precedes the hebetude so common at the close of the first, and during the second week of typhoid fever.

On the seventh day, May 10, the mental dullness had slightly increased, but he still answered questions promptly. The temperature continued the same. There was no cutaneous eruption, and no catarrhal symptoms except the cough, which was frequent, dry, and not accompanied by any auscultatory signs of disease. The tongue was coated light brown on the centre, but was clean along the edges; the lips were dry and chapped; the throat natural; the pulse 128; and there was no subsultus tendinum. The abdomen was not distended, but there was very slight tenderness, and distinct gurgling upon pressure over the right iliac fossa. There was no rose-colored eruption on the abdomen nor chest. The bowels had not been moved for several days, owing probably to the use of pulv. Doveri to quiet the cough. The nausea and vomiting had disappeared, but anorexia was still present. Slight bleeding from the nose occurred several times since the last note. The general appearance of the patient was decidedly that belonging to typhoid fever, although there were some of the usual prominent symptoms of that disease absent.

8th day. The bowels were opened with a teaspoonful of castor oil, and the stools presented the ochre color characteristic of typhoid fever.

9th day. The temperature to-day was lower than any time during the sickness. In the axilla it was 98.8° this morning, and 100.4° F. in the evening. This sudden fall of the body heat, with the irregular course of the disease, as shown by the other symptoms, in a child of strumous diathesis, excited fears of the approach of meningeal disease, and led to the frequent use of the thermometer, which was intrusted to the mother, who is an intelligent and observant person. This suspicion was further strengthened by a frequent rolling of the head from side to side by the patient, which was not before noticed, and by the very distinct presence of Trousseau's *tache cérébrale*, which Meigs and Pepper* mention as one of the diagnostic symptoms of tubercular meningitis.

10th day. Temperature at 9:30 a. m., 99.2°; at 12 m., 103°; 4:30 p. m., 103.2°; 6 p. m., 102.2°. Other symptoms same.

11th day. Temperature, 8:30 a. m., 100.8°; 11:45 a. m., 103.7°; 4:15 p. m., 102.8°; 7 p. m., 102.1; 8 p. m., 102.8°. At this time the symptoms noted on the seventh day all continued. During the interval there was occasional slight epistaxis; the cough continued dry and frequent, without any physical signs of throat or lung disease, except a few mucous ralés. There is still gurgling on pressure over the right iliac fossa, but no distension of the abdomen, and for the first time one rose-colored spot to be seen, which is located over the seat of the gurgling. The pulse is 128.

12th day. Temperature at 7:30 a. m., 100.2°; 2 p. m., 99.5°; 6 p. m., 104°; 9 p. m., 101.4°. This morning at 9:30 there was a typical measle eruption visible on the temples, behind the ears, in the throat, and on the soft palate, accompanied by a lachrymation and some running at the nose. The cough was worse, while the other symptoms were about the same as yesterday.

13th day. Temperature, 7:30 a. m., 102.6°; 11 a. m., 100.7°; 1 p. m., 102.8°; 4:30 p. m., 103.1°; 7:45 p. m., 104°. Measle eruption is very copious.

14th day. Temperature, 1 p. m., 99°.

17th day. The temperature has been the same as on the fourteenth day. The tongue is beginning to clean, and the patient is approaching convalescence. Since the last note of the bowels, they moved several times spontaneously, and the stools were ochre-colored. The patient's mind is clear to-day, but he is weak and still without appetite. The measle eruption began to disappear at the usual time and has nearly all gone.

The treatment was as follows: liquor ammoniæ acetatis, ʒj, and tinct. aconiti rad., gtt., ⅛, every two hours, followed by a drink of water. The face and upper part of the body were sponged with tepid water whenever the temperature approached 104° F. Dover's powder was given to quiet the cough and procure rest at night. After the end of the first week, cinchona gr. jss was given three times daily. As food, beef essence, milk, broths, soft-boiled rice, and bananas in small quantities were given.

---

* Edition of 1870.

On the 5th of May, two days after this child went to bed, the older one, Willie, who had just passed through measles, was taken with a distinctly intermittent fever, which on the third day became continuous, and was attended with about the same elevation of temperature as the other case. Anorexia, nausea, epistaxis, slight delirium and gurgling upon pressure over the right iliac fossa followed, and the same dry and harassing cough noted in the other case was present through the whole course of the disease. There was no rose-colored eruption nor diarrhœa, but the stools were ochre-colored. The treatment was the same as in the other case, excepting that no cinchona was given. Convalescence occurred on the fourteenth day.

At the time of the illness of these children there was an epidemic of measles in this city, and the older one, who had taken sick first, went through a typical attack. There can therefore be no doubt about the presence of the measle contagium.

The presence of typhoid fever poison at the same time was indicated by the manifestation of the disease in the elder child a week after his recovery from the measles. The only symptoms wanting to make this a typical case of typhoid fever were diarrhœa, tympanitis, and the rose-colored eruption on the skin. But, as already intimated, the use of the Dover's powder to palliate the cough may have averted the diarrhœa and tympanitis, which are usually associated in presence and intensity; and, furthermore, both are often absent in otherwise well-marked cases. Stokes mentions a case in which the disease ran a course of forty-three days, of which he says: "At no stage of the disease was there any swelling of the belly or tenderness there. There was no throbbing of the abdominal aorta, no rigidity of the recti muscles, no diarrhœa; the evacuations were all through healthy in character. In fact, in so far as the belly was concerned, not a single symptom could be detected from beginning to end. Not only was there a complete absence of any direct symptoms of intestinal disease in this perfectly marked case of typhoid, but also the patient took his food well, and it seemed perfectly to agree with him. On dissection, the lower third of the ileum showed a sheet of suppurating ulcers, with extensive destruction of the mucous membrane."

There are many other cases reported in which these symptoms were absent, but this one covers the point so fully and is given by so excellent an observer that no others need be cited. The absence of the rose-colored eruption and the intermittent character of the fever in the beginning of the disease are so frequent in children as not to require any special remarks.

If this second case of typhoid had not occurred, the first might have been mistaken for one of those irregular cases of measles in which the eruption appears late. Trousseau says the eruption may appear as late as the eighth day; Flint, the seventh or later; and Watson and Wood, as late as the tenth. In my experience it has not appeared later than the seventh day in the uncomplicated disease, and so late in one case only, that of an adult female. In this child the eruption appeared on the twelfth day of the disease. The fever which preceded it approached the character of typhoid more than measles. Epistaxis, headache, nausea and vomiting, and cough, may all be present in either measles or typhoid alone, but ochre-colored stool belongs only to the history of the latter. The general appearance of the patient, mental and physical, is also of diagnostic value in differentiating the two diseases; and the picture presented by this case before the eruption of measles was certainly that of typhoid fever.

In the light of recent investigations in the domain of disease germs, these cases might be made the subject of speculations as to the actions and reactions of different kinds of morbific matter simultaneously present in the human body; and with the advancement of our knowledge the record of them may, perhaps, serve a more practical purpose.

SOME SUGGESTIONS AS TO THE CARE OF THE INSANE PRIOR TO THEIR ADMISSION TO AN ASYLUM.

BY H. A. HUTCHINSON, M. D.,

Superintendent Western Pennsylvania Hospital for the Insane, Dixmont, Pa.

The care of the insane previous to their removal to an asylum is a responsibility demanding the wisest judgment and thought of those whose duty it is to be thus engaged.

In some of its forms, no disease is more amenable to treatment in its acute or early stages, and no fact than this is more widely recognized by alienists, and more earnestly advocated.

As the superintendent of one of our large State Hospitals for the Insane, I have had ample opportunity to observe the methods often employed in caring for this afflicted

class, and from these observations I am inclined to believe the reason a larger percentage of cures is not obtained in hospitals consists in the oftentimes indifferent treatment patients receive before their admission.

In many families there exists a prejudice in committing patients to an hospital, and to commit one of their afflicted members to an institution of this character is regarded as a disgrace both to the family and to the patient. A short time since, a patient was brought to this hospital, and the mother upon giving me the history of her daughter's case, remarked, "I have prayed heaven to spare me this greatest of all afflictions, the disgrace of having a child a lunatic and confined in an asylum."

As a result of this prejudice many insane are treated at home by their friends and family physician, the objectionable lunatic asylum, with its every facility for the care of just such cases, remaining an insurmountable barrier to the patient's rapidly departing chances of recovery.

When these endeavors have signally failed to restore the patient to reason, and the unfortunate being has become incurable and broken down in bodily health, he is taken to the hospital, and the friends accompanying him entreat the asylum physician to care for him kindly, and are surprised if an unfavorable prognosis be given.

Many who have no friends to care for them, or in whom the insanity is of a dangerous type and unsafe to be cared for at home, are arrested and placed in jail, their period of residence varying, sometimes but a few days or extending for several weeks, until the Court decides as to their insanity, and they are then committed to an asylum. It is at this very time, upon the first manifestations of the disease, the Court should at once direct their admission to a hospital; for their residence in jail where no means exist for their proper treatment, and as is often the case there are provided the barest necessities of life, is the time when judicious medical treatment and the care and comforts of a well appointed institution would effect their restoration.

Female patients have frequently complained to me of the disregard of the proprieties of life during their confinement in jail. No jail should be without a matron, whose duty should be to care for the female inmates.

Of forty-five patients committed to this hospital by order of the Courts of the thirteen counties comprising this asylum district, sixteen were committed directly from the jails, and of this number but three recovered,
though a large proportion were acute cases.

A no less important factor in the care of the insane is the time and manner of their removal thereto. The larger number of patients when admitted to our hospitals are in poor bodily health, and there can be no doubt the condition of many is made worse by the fatigue and exposure incident to the journey.

In acute cases the exhaustion following is often fatal. In this hospital fifty-nine deaths occurred during the past year; eight died whose period of residence was but twelve days, and two were in a dying condition at the time of their admission, and died within seventy-two hours after. One of these patients, suffering from acute melancholia, was in a state of collapse when admitted; the other, who had typhoid fever, was beyond the aid of all human skill when brought to the door.

Female patients should always be accompanied by some female friend, in whom the patient has confidence, and to whom she can make known her wants and necessities; the total disregard of these proprieties, as shown so frequently in female patients brought to asylums in the custody of men and who are perhaps strangers, is often attended with great mental excitement, prolonging the insanity, and operating largely against possible recovery.

All superintendents will agree with me. I think, in regard to the difficulty in obtaining a history of patients admitted to their hospitals, so often the friends hesitate or dislike to state the particulars of the patient's trouble, thereby embarrassing the physician in his future treatment of the case, and also acting as a hindrance to the patient's recovery.

This hesitancy on the part of friends of patients is universal, as the records of this Institution prove. In preparing this paper I have referred only to the prominent defects in the present methods of providing for this class of humanity; but I feel assured "until the present laws controlling the admission of patients are amended, making provision for the overcoming of these evils, the mortality in the State Hospitals will be necessarily large, and the number of cures materially lessened."

—Japan has been mapped out into six divisions, and a medical college is to be established in each division.

Medical Societies.

CHICAGO MEDICAL SOCIETY.

(*Concluded from page* 622.)

The President asked if it was not possible that some portion of the upper wall of the vagina was drawn upwards and backwards by the bladder, and what was taken to be a continuous wall of the bladder might be a part of the vagina. He had seen a case where there was a large laceration into the bladder, and the opening seemed one cavity with continuous walls, but the flap thrown backwards was post-vaginal, and it was found that this flap could be drawn up and into its position.

Dr. E. C. Dudley, in answer to questions, said that the loss of tissue at the base of the bladder from sloughing differs from that by incision. In the latter case the ureters would perhaps be included in the excised tissue, but it is seldom that a slough of the base of the bladder in vesico-vaginal fistula, however extensive, destroys the connection between the bladder and kidneys. Even if the points through which the ureters penetrate the mucous coat of the bladder be lost, it is yet possible their openings into the bladder may be preserved, because the ureters penetrate the muscular coats nearly an inch from their normal points of opening through the mucous coats of the bladder, and run obliquely between the two coats for a distance of nearly an inch. In this case, as in many cases of loss of entire base of bladder reported by Emmet, the openings of the ureter were on either side, at the very margins of the fistulous opening. The operation was performed at Morton, Ill., in the presence of Dr. Harris, of that place, and Dr. Mansfield, of Metamora. Dr. Parkes's surmises with reference to the vaginal wall could hardly be correct, because this, together with the anterior wall of the cervix uteri up to the internal os, had sloughed away. His surmise might be correct with reference to certain tissues between the bladder and the cervix uteri which might have retracted and become adherent by inflammation, so as actually to form a portion of the bladder wall. Moreover, there is always a very decided difference in color and appearance between vaginal and bladder tissue, and the tissue in this case was to all appearance like the tissue of the rest of the bladder, and to the touch gave the sensation of a thin wall. Dr. Baker, of Boston, reports a case similar to this in that he introduced sutures into the bladder tissue, but so close to the cervix uteri as not to draw down any portion of the interior of the bladder, to be used as material in place of the lost vaginal wall.

Dr. W. L. Axford reported

A Case of Removal of the Entire Lower Jaw through the Mouth.

Harry T., aged 5. Admitted to St. Joseph's Orphan Asylum in November, 1885. It was noticed that his mouth was frequently swollen and sore. Child very much emaciated. In January, 1886, he had measles. Tedious convalescence followed. Came under observation about February 1. Weak and thin. Lower part of face very much swollen. Breath offensive. Symphisis of jaw bare. Could not examine further at this time. Pulse 120 to 130. Put the child on supporting treatment, hoping to get him in condition for an operation. No improvement at the end of two weeks. February 16 the patient was anæsthetized and the mouth explored. Found the jaw on either side stripped of its periosteum back to the masseters. Determined to attempt removal through the mouth. Any cutting operation involving the loss of much blood would have been fatal at once. Divided the jaw on either side of the symphysis with bone pliers, and thus removed a large portion of the body. Seizing the remaining pieces with sequestrum forceps and making moderate traction, they were easily enucleated by the index finger of the left hand. Not more than a tablespoonful of blood was lost. Patient rallied well. Some reaction on second day. On third day the pulse had dropped to 116, and with exception of a swollen parotid on the left side, the child was in better conditton than before the operation; so much so that a recovery was confidently predicted. A severe attack of diarrhœa occurring on the morning of the fourth day was followed by death in thirty-six hours.

Dr. Arnold P. Gilmore exhibited a patient on whom he had performed an operation for

Symblepharon of the Lower Lid,

due to a burn by molten iron, and in which three plastic operations had been unsuccessfully performed. Nine months previously the entire lower lid, from external to internal canthus, was adherent to the eyeball, covering almost the entire cornea. This triangular-shaped tissue was covered by a pale membrane of cicatricial tissue. The operator first detached the lower lid and transplanted the conjunctiva of a rabbit. For six weeks the operation was apparently suc-

cessful, but after an absence of two months from the city he found the lid was again becoming adherent. Six weeks previously Dr. Gilmore made a thorough dissection, freeing the lid and making a deep cul-de-sac, leaving the upper half of the eyeball covered by mucous membrane and the lower half bare. A semicircular band of conjunctiva, one-third inch wide, was dissected close to the cornea above, leaving a bridge of tissue at each end. This band was dropped into the cul-de-sac below and carefully stitched to the ball. A semicircular plate of silver long enough to fill the space between the external and internal canthi, with two holes at the circumference, one-half inch apart, threaded with silver wire, was dropped into the cul-de-sac to prevent adhesions, and fastened by bringing the wires through upon the face and fastening them by small lead plates and perforated shot. For this operation Dr. Gilmore claimed priority. The object of the operation was neither to improve the appearance of the eye nor to restore vision, but to relieve the irritation of the other eye, by allowing coördinate movements of the two eyes. There was enough clear cornea left to make an artificial pupil in case the patient ever lost his well eye. There was little reaction, and at no time much pus, while the well eye has grown stronger in spite of the presence of the plate.

Dr. Tilley thanked Dr. Gilmore for showing this case, but thought that if the Doctor were to go out of town again for two months as in the first instance, he would find at the expiration of that time the conditions relatively very much the same as on his return after the first operation. He thought there was little fundamental advantage likely to be associated with the operation, as he thought that in a short time the wire and plate would cause a certain amount of atrophy of the intervening tissue, and the plate be forced up and out of position, making the operation of no avail. If he was so unfortunate personally as to be placed in a similar position, he would have his eye enucleated.

Dr. E. L. Holmes thought it unwise to say that a certain thing could not possibly be accomplished, but he had been through the experience of putting in plates, and seeing it done, and never saw one permanently successful. It is different with a very narrow symblepharon in which the globe and eyelid are grown together, where by dissection and transplanting the mucous membrane excellent results may be attained. He thought the plate would irritate the cicatricial tissue and cause it to be very much thickened, and after a few months, or weeks even, when everything is removed, there will be the same tendency to creep over the cornea and make adhesions with a broad union. He thought it absolutely impossible to get an artificial eye to fit. A very small eye might be used and temporarily make it appear that the patient was better off, but that small eye will often irritate and cause the cicatrix to increase.

The president thought this case one of the same category that is so troublesome to the general surgeon, the improvement of deformities from cicatrices of all kinds, in which relief comes only in the way that Dr. Dudley has applied in gynecology, after the divided cicatrix has been separated as widely as possible, by drawing together the healthy skin or tissue between the two ends of the divided cicatrix. This method has long been in use in general surgery. So far as his experience went, the application of any foreign body between these divided surfaces has never been followed by success, so far as prevention of contraction goes.

The president presented an

Encapsulated Sarcoma of the Thigh.

It had been in alcohol for some time, and was reduced about one-third in size. It had grown the full extent shown in three months, and was removed from an old lady aged 69. It was found growing upon the posterior part of the upper portion of the thigh; was a firm, smooth tumor to the touch, and as far as external manipulations determined, could not be distinguished positively from other parts of the surrounding tissues. He could not determine whether it was or not attached to the bone, but from external appearances it was diagnosticated to be of a malignant type. The external surface was crossed by a large number of varicose veins. After removal it was shown to be a sarcoma. The interesting point was the rapidity of its growth. He thought it a singular coincidence that about a year previous he had removed a similar tumor from the upper portion of the left arm of an old man of 72 years, which had also grown to the full size in three months. Upon exposing the tumor a perfect capsule was reached, and it was easily enucleated from its bed.

BALTIMORE GYNÆCOLOGICAL AND OBSTETRICAL SOCIETY.

Regular meeting held February 9, 1886. The President, George W. Miltenberger,

M. D., in the chair. William E. Moseley, M. D., Secretary.

Dr. A. F. Erich read the following paper:

Diagnosis of Fibro-Cystic Tumor of the Uterus—Laparotomy and Supra-Vaginal Amputation of Uterus.

Mrs. A. McN., American, aged forty years, widow, entered the Maryland Woman's Hospital December 15, 1885. Married when nineteen years old; she has had no children nor abortions. She menstruated first when thirteen years old, generally every four weeks, sometimes the interval being but three weeks. Amount usually small, and the duration four to five days. She is very anæmic. Five years ago she first noticed a hard tumor the size of a hen's egg in the lower portion of her abdomen; it grew rapidly during the first two years and a half; since then, more slowly. It varied in size, and had lately become somewhat smaller. Has had bloody discharges from her vagina, lasting six weeks, and has at times gone as many weeks without any discharge. Has frequently suffered from pains resembling labor. Her health has been gradually growing worse ever since she first noticed the tumor. Has also been subject to attacks of nausea, vomiting, and diarrhœa. Physical examination revealed a tumor the shape of an enlarged uterus, extending from the pubes to a little above the umbilicus, movable and continuous with the cervix uteri. The depth of the uterus, as measured with the probe, was five inches. Temperature, pulse, and respiration normal. The consistency of the tumor seeming rather softer than that of a fibroma, the aspirator needle was introduced and about a fluid drachm of a colorless, serum-like fluid was obtained, which, upon microscopical examination (by Dr. Keirle) did not furnish any characteristic appearances that were calculated to assist in the diagnosis. The aspiration was not followed by any unpleasant effects. The diagnosis arrrived at was interstitial fibro-cystic tumor of the uterus, adopting the definition as given as given in Prof. Th. Billroth's "Handbuch der Frauenkrankheiten," band i, abschnitt iii, seite 102, according to which all fibroid tumors that contain collections of fluid within their stroma are fibro-cystic tumors. These include lymphangioma, myoma-telangiektodes s. caremosum (Virchow*), and myxomyoma, of which latter Gusserow says (page 103 of Billroth's work above quoted) that microscopically it would be difficult to distinguish this form from sarcoma. The great danger of supra-vaginal amputation of the uterus (the only radical cure of the case) being fully stated to the patient, she elected to take the risk, rather than to continue to lead the life she had been leading. The patient being extremely anæmic, the palpebral conjunctiva being perfectly white, she was put upon a preparatory treatment consisting principally of good food, iron, and quinia, until after the expiration of six weeks she seemed to be strong enough to make a successful operation possible. The operation was done February first, under all the usual antiseptic precautions, and occupied three hours. The abdominal incision made in the linea alba, extending from an inch and a half above the pubes to the umbilicus, had to be extended to a little over an inch above the umbilicus before the enlarged uterus could be rolled out. Both ovaries, considerably enlarged, rolled out with it. Finding the diagnosis verified and no adhesions present, an Esmarch gum tube of the thickness of a little finger was tied firmly around the cervix as low down as practicable, including a considerable portion of the broad ligaments.

The greater portion of the uterus was then removed, taking care to leave enough of the cervix to prevent the gum tube from slipping. The broad ligaments were next secured by ligatures before they had time to slip from under the gum tube, which they are apt to do. As much of the cervix as could be safely removed was then trimmed out in the shape of a funnel with thin edges. These edges were brought together anteroposteriorlv, by first a row of deep sutures to prevent bleeding, and second, a row of superficial sutures, to bring the edges of the peritoneum in good apposition. Being unwilling to trust a mass ligature around so thick and rigid a stump as the remnant of the cervix presented, much time was spent in arresting hemorrhage from the stump by the introduction of deep sutures. The rubber tube had to be loosened and tightened many times before all the bleeding points had been thus secured. The blood lost during the whole operation could not, however, have amounted to more than a few ounces. The vagina was then carefully washed out with the bichloride of mercury solution, an opening made at the lowest point in Douglas' cul-de-sac, and a rubber drainage-tube provided with a cross-bar, to prevent it from slipping out, and long enough to reach from this space to the vulva, inserted. The vagina was filled with salicylated cotton, and the external opening of the drainage-tube covered

*Geschwulstlehre iii., p. 124.

with the same material in order to exclude the air. The abdominal incision was closed in the now usual manner, deep and superficial silk sutures, and dressed antiseptically. Fully realizing the gravity of the operation, only such assistants as were absolutely necessary were admitted to the operating-room, in order to make the risk from infection as small as possible. Prof. Rohe administered the ether, and Dr. Clair, the resident physician, the three house students, Messrs. Lindley, Wise, and Robertson, with the matron, Mrs. Warner, all dressed in freshly-washed linen, were all that were permitted to be present. The subjoined pulse and temperature chart furnishes the subsequent history in a condensed form.

Dr. Keirle's report of the necropsy gives as the cause of death cardiac asthenia and thrombosis, and says that the heart was so flabby as to flatten out of shape when laid upon the table. His report also shows that there was no secondary hemorrhage, that the drainage had been efficient, and that septicæmia had been prevented, as shown by the absence of decomposing fluid in the abdominal cavity, the temperature and pulse changes, and the fact that a firm clot of blood was found in the heart and pulmonary vessels, while after death from septicæmia, the blood is generally found of the consistency of tar. The manner of operating was that described by A. Martin in his "Pathologie und Therapie der Frauenkrankheiten," with such slight modifications as personal experience suggested, or were made necessary by the conditions under which the operation was done. Martin places a ligature around the cervical stump, to which, with my experience with a catgut tourniquet in cervix operations, I felt I had no right to trust the life of a patient. As I was not able to secure a drainage-tube provided with a cross-bar as he describes, I was compelled to extemporize one by cutting a hole through a gum tube near its end, and then forming a cross-bar by splitting a small piece of the same tube, and passing one of these pieces through the holes formed at the upper end of the drainage-tube. This piece, turned with its concave surface downwards, gave an opening on each side of the tube immediately under the cross-bar. The opening in Douglas's cul-de-sac, for the passage of the tube, was made by pushing the point of a uterine dressing forceps, with a boring motion, through the peritoneo-vaginal septum, from the vagina into Douglas's space, the fingers of the left hand being used to make counter pressure. This instrument being so very blunt, the opening was made without the loss of blood. The lower end of the tube was now seized between the blades of the forceps and drawn down until its cross-bar rested upon the floor of the space. The necessity of the tube was made manifest by an almost constant dribbling of bloody serum during the first twenty-four hours. The tube was removed on the morning of the fourth day. In reference to the condition of the abdominal cavity, Dr. Keirle reports, "there was no attempt at union of the abdominal incision, the lower half of which is discolored. The stump of uterus is observed united by sutures and lymph. Injection with two-ounce glass syringe, nozzle introduced through cervical canal, does not, until after fourth trial, spirt in three fine jets through incision." Around the opening made for the drainage-tube he found "a layer of lymph (fibrin), of irregular superficies, which extends thence on the pelvic peritoneum 2 cm. area. Fibrin also agglutinates some coils of small intestines to uterine stump. This is a limited pelvic peritonitis. No further inflammation exists in the abdominal cavity, in which the other organs and structures are normal." The tumor was imbedded in the anterior wall and fundus of the uterus; the thickness of the anterior wall being six inches, that of the posterior only three-quarters of an inch. Weight of the whole uterus and tumor three pounds and eight ounces. Upon section the tumor presented a pink-colored transparent tissue, seemingly consisting of a delicate network of fibres and capillary vessels separated by transparent fluid, looking very much like a section through connective tissue in œdema, and corresponding very nearly to a description of myxomyoma as given by Virchow.

Dr. N. G. Kierle, the pathologist to the hospital, states: *"Its microscopic histology is that of the medium-sized spindle-cell sarcoma."

First day—6:30 p. m., temperature 96°, pulse 120; 9:30 p. m., temperature 98°, pulse 108.

Second day—10:00 a. m., temperature 101°, pulse 110; 4:00 p. m., temperature 100°, pulse 114; 10:00 p. m., temperature 101.6°, pulse 130.

Third day—10:00 a. m., temperature 102.2°, pulse 120; 4:00 p. m., temperature 100.8°, pulse 130; 10:00 p. m., temperature 101°, pulse 114.

Fourth day—10:00 a. m., temperature 103°, pulse 120; 12:30 p. m., temperature

* The microscopical examination was made after the case was reported.

104°, pulse 150; 2:30 p. m., temperature 104.8°, pulse imperceptible; 3:13 p. m., death.

Dr. W. P. Chunn asked Dr. Erich the character of the fluid withdrawn by aspiration; did it coagulate on exposure to air? He had always considered that if the fluid coagulated, it was a proof of fibro-cystic tumor, as the rule, to which he knew there were exceptions, was that fibro-cystic fluid was blood minus its corpuscles, and would coagulate when exposed to the air.

Dr. Erich answered that, as the amount of fluid obtained was very small, and as it was wanted for microscopical examination, he did not test its coagulability. As he said in his paper, the microscopical examination threw no special light on the diagnosis.

Dr. T. A. Ashley said that Dr. Erich had stated that he had used thorough antiseptic precautions in this operation. He would like to ask the doctor what antiseptic method he had employed.

Dr. Erich replied that the ceiling, walls, and floor of the patient's room were swept and washed and then sprayed with a carbolic acid solution. Only those required as assistants were permitted to be present, and all were dressed in freshly-washed linen, their finger-nails cut, and hands thoroughly cleaned. Carbolic acid solution was used for instruments, and a 1 to 2000 solution of bichloride of mercury for sponges, etc. The dressings for abdominal wound and vagina were described in the paper.

Dr. Ashley said that the object of his question was to elicit some discussion on the use of antiseptics in abdominal surgery. As is well known, opinions differ very widely among European abdominal surgeons in respect to the use of antiseptic agents within the abdominal cavity. While thorough Listerian principles, including the use of the spray, are enjoyed by a surgeon of Mr. Thornton's acknowledged ability and experience, all antiseptic agents are discarded by so successful an operator as Mr. Lawson Tait. One fact is clear amid all the confusion respecting the details of antisepticians, and that is the great value of absolute cleanliness, which is the essence of Mr. Lister's teachings. Modern statistics show the great value of these principles in abdominal surgery, and he would be indeed a bold operator who failed to apply these principles, modified only as to details.

Dr. Chunn questioned the advisability of introducing a drainage tube in those cases where there were no adhesions, and consequently no blood or fluid of any kind left in the peritoneal cavity. This opinion he based upon the teachings of Mr. Keith. He considered that if any fluid did collect in Douglas' space, it could be easily detected and gotten rid of. He was of the opinion that a woman of forty with a growth like that shown could be tided over until after the menopause, which could not have been many years distant in the case reported.

Dr. H. P. C. Wilson questioned the report that some distinguished operators entirely ignored antiseptics. Some, he was aware, did not use the spray, but he was under the impression that they were careful to see that all sponges, instruments, and appliances that had been used in one operation were rendered thoroughly antiseptic before being used in another. Several acids, bichloride of mercury, and other agents, were antiseptic, and if any of them were used to guard against septicæmia, those employing them could not be said to be opposed to antiseptics in abdominal surgery. As far as he personally was concerned, he still had great faith in antiseptics, especially in hospital practice, and he favored the use of the spray in such cases, having it stopped only just before beginning the operation. He never could understand why we should be so careful in disinfecting sponges, and not use as great precaution to render antiseptic the air around hospital operations. In one case he did a laparotomy upon a patient at the same time that there was a case of erysipelas in the next room, and the result was uninterrupted recovery. At another time he removed an ovarian tumor from a woman who occupied the same room and bedstead that had been vacated only ten days before by a patient having a sloughing fibroid, from which the stench was so great that it was nauseating to enter her room, and rendered the air of the whole floor offensive. In this room the carbolic spray was used liberally for several hours before the operation, and especially under, around, and in the bed. In some cases he washes out the abdominal cavity with bichloride solution before closing the incision.

Dr. Ashley said he had not had any opportunity of seeing Mr. Tait operate, and so was not personally familiar with his methods, but Mr. Tait had published the fact that he had no faith in the so-called antiseptic agents, and believed they did more harm than good. At one time he (Mr. Tait) had practiced the Listerian ideas in all their details, but they disappointed him, and he gave them up. He took water from the tap and put it into the basin for the sponges, over the instruments and into the abdomen, but he practiced the most rigid enforcement of cleanliness. Dr.

Ashley had recently, through the courtesy of Dr. Chambers, the resident physician, had an opportunity to examine Dr. T. G. Thomas's private hospital from cellar to garret. Every idea that prevails in its construction and management has reference to purity of air, scrupulous cleanliness, and absolute comfort. But, with every modern convenience for ventilating, heating, and lighting, Dr. Thomas still employed a thorough system of antisepsis, and in every detail of his operative work reference is had to disinfection and absolute cleanliness. Dr. Ashby expressed the opinion that, in our country at least, omission of antiseptic precautions in abdominal surgery would mean an increased death rate, and that no surgeon could, in justice to his patient or to his own reputation, afford to hazard an operation within the abdominal cavity without using those methods of antisepticism that are expressed in the Listerian idea.

Dr. A. asked permission to relate the following case, which he considered of interest in connection with the case reported by Dr. Erich. The patient was a negro woman, age 31, and had been married between nine and ten years. Her youngest child was about 8 years old. For four or five years past she has lost considerable blood during menstruation, and has noticed an enlargement of the abdomen, but attributed the latter to taking on flesh. For several months past menstruation has been very profuse, generally lasting about eight days. During the inter-menstrual period she has a discharge from the vagina of a clear watery fluid, and ranging in amount from a teacupful to a pint in twenty-four hours. The discharge of fluid is spasmodic in character, deluging her clothing. Her general health is at about par. Physical examination reveals a globular tumor about the size of a uterus at the fifth month of pregnancy. The tumor has thick, dense walls, and is largest at its upper part. The cervix uteri is normal in size, and full. The sound enters the uterus 5½ inches, is grasped tightly by the lower segment, but rotates freely in the cavity near the fundus. Dr. A.'s diagnosis is a fibroid of the uterus undergoing cystic degeneration. The indications for treatment are palliative, as in the present condition of the patient no operative procedure would be justifiable. The case is of interest from the fact that the woman's health remains so good, and that the cyst should have opened into the uterine cavity and allowed its contents to discharge as described.

Dr. W. E. Moseley thought one great source of misunderstanding in regard to antisepticism came from the inclination people showed to limit disinfectants to the so-called antiseptic solutions and powders. Those surgeons who decry most loudly the use of antiseptic precautions are very careful to expose their sponges, etc., to a high degree of heat before using, and thereby make use of the most powerful means of rendering them aseptic. Live or free dry steam is found to be the most effective agent in disinfecting on a large scale. The numerous antiseptic preparations have their places, but many of them are almost or quite useless, unless used in very concentrated form, and others are poisonous or irritating, and caution must be exercised in their application.

Dr. Erich said that in institutions having arrangements for disinfection by heat much could be done by that means, but in our own hospitals he thought it necessary to have recourse to antiseptic fluids.

If any question arose as to the diagnosis of the case reported, he would refer those present to Billroth's work mentioned in his paper, and ask a comparison of the specimen with the description found there. He thought many cases were diagnosticated fibro-cysts which were not really such, as, for instance, one operated upon by himself, which proved to be an old abscess of a broad ligament. The rule laid down by authorities is that fibro-cysts contain either blood, serum, or lymph, and that the diagnostic value of coagulability of the fluid contents depended entirely upon the character of cystic degeneration. In the seventy cases of fibro-cystic tumors collected by O. Hear, only eleven contained fluid coagulating spontaneously.

Regarding the question, whether the removal of a growth, the size of that shown, was a justifiable procedure or not, he thought the social position of the patient had much to do. He considered that a rich woman would have been able to endure the growth for a considerable time, even until the menopause, as she could place herself among the best surroundings and have proper care; but, in the case in hand, the woman was poor and obliged to earn her own living, which the growth prevented her from doing. He had represented fully to his patient all the dangers attending the operation, and she had insisted upon undergoing it. In such cases he thought we had no right to refuse to operate.

He considered the detection of a small amount of fluid in Douglas' cul-de-sac, unless

encapsulated, an impossibility, as free fluid would recede upon the slightest pressure from without. The peculiar form of drainage he had adopted was that recommended by Martin of Berlin, and had been used by him in several cases with the best results.

Dr. P. C. Williams asked for an explanation of the fact that, in a woman dying of asthenia, there should be a temperature of 96° F. immediately after the operation, and that it should rise each day until it reached 104.8° F. on the day of her death. Would not such a range of temperature indicate some inflammatory or septic complication?

Dr. Erich replied that he considered it an advantage to have a slight rise of temperature after an operation, as he thought it indicated a greater amount of vitality in the patient than if it had a tendency to remain sub-normal. That with the closure of the peritoneal edges by the exudation of lymph, there must be some local peritonitis.

Drs. Ashley and H. P. C. Wilson emphasized the importance of taking the patient's social position into account in considering the advisability of any operative procedure, and agreed with Dr. Erich in his conclusions.

Dr. Robert T. Wilson exhibited some surgical needles, the invention of David Genese, D. D. S., of this city. Dr. Genese calls his needles "Iridinized Platina Needles." They are made with a platinized gold head, hardened under hydraulic pressure. Needles can be made by this process of any shape or size, and they are said to be indestructible under the pressure of forceps or the action of acids, but can be bent to any desirable curve.

Dr. Moseley thought that, judging from the needles shown, they would be useless in any operation where much force would be required for their introduction. Strong steel needles will often bend and sometimes break in the hands of skillful operators, and in such cases a needle which can be bent as easily as the samples would be of absolutely no value. They might be of use in a limited class of cases where their introduction would require but little force.

Dr. Erich said that the danger of the steel needle breaking at the eye could be obviated by heating it at that end and allowing it to cool slowly. This would not interfere much with the temper of the needle at its point.

In his operations for lacerated cervix he uses a tourniquet, and supposes he is a marked exception to the rule in so doing. The instrument he uses is his own device, is like a light ecraseur with catgut for a chain. His special reason for using it, aside from preventing hemorrhage, is that it so benumbs the cervix that he does not need to use any other means of producing anæsthesia, except in the case of very nervous women, when he has recourse to ether or chloroform. The use of this instrument demonstrated to him the fact that, after the parts had been ligated for some time, they would shrink, allowing the bleeding to return and requiring the tightening of the tourniquet, and had thus taught him not to depend upon a ligature in supra-vaginal amputation of the uterus.

Dr. B. B. Browne said that in many cases of deep laceration of the cervix, extending up to and beyond the vaginal junction, he thought it would be difficult if not impracticable to apply the tourniquet above the seat of laceration. We asked Dr. Erich how, in such cases, he prevented cutting the ligature of the tourniquet while removing the cicatricial tissue from the angles.

Dr. Ashley stated that he continued to employ the tourniquet in a certain number of cases. He had found it useful in those cases where the cervix uteri was much elongated and where there was hyperplasia and congestion of the cervical flaps. He could verify the assertion made by Dr. Erich as to the necessity of constantly tightening the loop of the tourniquet in consequence of a shrinkage of the tissues. He had never employed catgut as a loop, but used very flexible wire.

Dr. H. P. C. Wilson could not see how, in those cases in which the laceration extended up to the vaginal junction, it would be possible to apply the tourniquet so as to clean out the angles without cutting the catgut cord. He thought that in certain special cases the instrument might be of use.

Dr. Erich replied, that where the uterus was easily movable, by drawing the cervix well down, the tourniquet could be applied above the angles of the deep laceration, even above the internal os. That the only cases in which he had difficulty, were those in which there was a very short and conical cervix, or the uterus was fixed, so that it could not be drawn down far enough.

—The adulteration of lupulin with sand is largely practiced in England, according to J. S. Ward. In a paper read before the Liverpool Chemists' Association, he reports that the results of analysis of four samples obtained from houses of good repute justifies the belief that the lupulin of commerce will not answer the official tests. The percentages not soluble in ether were 55.24, 41.49, 40.64, and 39.41 respectively, and of ash 27.01, 29.10, 30.86, and 31.42 respectively.

EDITORIAL DEPARTMENT.

PERISCOPE.

Disinfectants.

The following disinfectants were recommended by the Committee of the American Public Health Association in their report submitted to the Association at the meeting held in Washington, in December, 1885:

FOR EXCRETA.

(*a*) In the sick-room:

For spore-containing material;

1. Chloride of lime in solution, four per cent.
2. Mercuric chloride in solution, 1:500.†

In the absence of spores:

3. Carbolic acid in solution, five per cent.
4. Sulphate of copper in solution, five per cent.
5. Chloride of zinc in solution, ten per cent.

(*b*) In privy vaults:

Mercuric chloride in solution 1 : 500.*

(*c*) For the disinfection and deodorization of the surface of masses of organic material in privy vaults, etc.:

Chloride of lime in powders.‡

FOR CLOTHING, BEDDING, ETC.

(*a*) Soiled underclothing, bed-linen, etc.:

1. Destruction by fire, if of little value.
2. Boiling for at least half hour.
3. Immersion in a 2 per cent. solution of mercuric chloride of the strength of 1 : 2000 for four hours.*
4. Immersion in a 2 per cent. solution of carbolic acid for four hours.

(*b*) Outer garments of wool or silk, and similar articles, which would be injured by immersion in boiling water or in a disinfecting solution:

1. Exposure to dry heat at a temperature of 110° C. (230° Fahr.) for two hours.
2. Fumigation with sulphurous acid gas for at least twelve hours, the clothing being freely exposed, and the gas present in the disinfection chamber in the proportion of four volumes per cent.

(*c*) Mattresses and blankets soiled by the discharges of the sick:

1. Destruction by fire.
2. Exposure to super-heated steam—25 pounds pressure—for one hour. (Mattresses to have the cover removed or freely opened.)
3. Immersion in boiling water for one hour.
4. Immersion in the blue solution (mercuric chloride and sulphate of copper) two fluid ounces to the gallon of water.

FURNITURE AND ARTICLES OF WOOD, LEATHER, AND PORCELAIN.*

Washing, several times repeated, with:

1. Solution of mercuric chloride 1:1000. (The blue solution, four ounces to the gallon of water, may be used.)
2. Solution of chloride of lime, one per cent.
3. Solution of carbolic acid, two per cent.

FOR THE PERSON.

The hands and general surface of the body of attendants of the sick, and of convalescents at the time of their discharge:

1. Solution of chlorinated soda diluted with nine parts of water (1:10).
2. Carbolic acid, two per cent. solution.
3. Mercuric chloride, 1:1000; recommended only for hands, or for washing away infectious material from a limited area, not as a bath for the entire surface of the body.

FOR THE DEAD.

Envelop the body in a sheet thoroughly saturated with:

1. Chloride of lime in solution, four per cent.
2. Mercuric chloride in solution, 1:500.
3. Carbolic acid in solution, five per cent.

*The addition of an equal quantity of potassium permanganate as a deodorant, and to give color to the solution, is to be recommended. (Standard Solution No. 2.)

†A concentrated solution containing four ounces of mercuric chloride and one pound of cupric sulphate to the gallon of water is recommended as a *standard solution*. Eight ounces of this solution to the gallon of water will give a dilute solution for the disinfection of excreta, containing about 1:500 of mercuric chloride and 1:125 of cupric sulphate.

‡For this purpose the chloride of lime may be diluted with plaster-of-Paris, or with clean, well-dried sand, in the proportion of one part to nine.

§The blue solution containing sulphate of copper, diluted by adding two ounces of the concentrated solution to a gallon of water, may be used for this purpose.

*For articles of metal, use Solution No. 3.

Diphtheria not a Sewer-Gas Disease.

The *Med. Record* says that Dr. Erwin F. Smith, in an elaborate paper on the "Influence of Sewerage and Water-supply on the Death-rate in Cities" (Report of Michigan State Board of Health, 1885), claims to establish the three following propositions:

1. Typhoid fever and cholera decrease in proportion as a city is well sewered.

2. There is no direct relation between diphtheria and sewers.

3. The general death-rate falls after the sewering of a city, and, other things being equal, never again reaches the maximum of its ante-sewered condition.

4. The cost of sanitation is incomparably less than that in sickness and death resulting from neglect of sanitation.

Dr. Smith's statements with regard to diphtheria and sewerage are:

"1. Diphtheria is as frequent in the country as in the city, *i. e.*, in non-sewered as in sewered districts.

"2. Diphtheria has been more frequent and fatal in certain rural districts than in any city whatsoever.

"3. Diphtheria is not more frequent or fatal in sewered cities than in unsewered ones.

"4. Of the given cities, equally well- or ill-sewered, diphtheria, during a long series of years, may be widely prevalent in the one and rare in the other.

"5. Certain sewered cities have never suffered seriously from diphtheria, while others have been afflicted very much worse in recent years (*i. e.*, since the houses have been protected from sewer-air), than formerly, when with the same sewers, but much less perfect plumbing, flushing, and ventilation, the sewer air found its way into a majority of the houses.

"6. When an epidemic of diphtheria appears in a city, the sewered and unsewered portions generally suffer alike.

"7. No relation of interdependence can be traced between diphtheria and the sanitary state of a city, such, for example, as enables us to predict with almost absolute certainty the typhoid fever mortality of a city from a knowledge of its sanitary condition, or conversely, the sanitary condition from its typhoid mortality.

"8. The annual mortality from diphtheria fluctuates greatly, and this, too, in cities where the sanitary conditions are very nearly constant.

"9. Diphtheria is a disease of cold weather, being most active when putrefactive decomposition in sewers is presumably least so.

"10. Diphtheria is a contagious disease, transmissible from person to person and place to place, like small-pox and scarlet fever.

"11. The closing of schools and other places of public gathering checks an epidemic; and the isolation of the sick from the well, with the subsequent proper disinfection of the sick-room and its contents, extinguishes it.

"12. The data relied upon to prove a connection between sewerage and diphtheria either cover too short a period to be trustworthy, or are drawn from single cities having incomplete and defective sewerage.

"If these propositions be true, it follows as a necessary corollary that there is no direct relation between sewers and diphtheria."

These conclusions are based upon a study of the vital statistics of a large number of European and American cities and districts.

These are not at variance with any settled views as regards the origin of diphtheria. Many individuals have reported cases which seemed to originate from sewer-gas, but the most careful authorities have not been disposed to attribute to sewer-gas more than a predisposing influence.

A Marvelous Case of Tubal Pregnancy.

Dr. N. T. Tauski thus writes in the *Obstetric Gazette:*

Mrs. H. D.——, æt. 38, mother of seven children, on June 29, ult., complained to me of absence of her menses, loss of appetite, sleeplessness, and general malaise. Prescribed hot mustard baths and quin. sulph. in five-grain doses three times a day, with otherwise good results except the menstrual trouble.

She was very much afraid of getting pregnant again, as the attending physician to her last child gave the opinion that she would not outlive another confinement.

Examination did, indeed, not reveal any state of pregnancy, there being a normal condition of the uterus. The usual remedies for suppressed menstruation proved useless; the lady is, in the meantime, complaining of puffiness and swelling on the left side, just under the ribs, especially towards evenings, so that she could breathe only with difficulty.

Examined again July 19. Same state of the organ, save a small tumor-like elevation near the fundus, in the region of the left ovary. It must be a tubal pregnancy or a tumor, I stated to her, and advised further examination by other physicians of experience and authority. Her friends urged her to try their doctors. Among them was a certain Mrs. Brackmann, alias Bergmann, a "lady doctor," in Elmwood Place, two miles north from here. This "doctor," after a careful examination of Mrs. H. D——'s urine, pronounced her to be pregnant, with the fœtus in the abdomen, and floating in an unusual quantity of fluids. But our patient did not seem to trust the "doctor's" art of telling the kind of pregnancy by a mere looking at the waters, and concluded to fol-

low my advice. She consulted Dr. Thad A. Reamy, whose opinion was that she had either a tumor or abdominal pregnancy, he then being unable to detect any signs of fœtal life. This was about the middle of October last. His second examination, however, dispelled the theory of tumor, as the child was playing quite palpably, but, according to all indications, in the abdomen.

November 11 she was again examined by Dr. Reamy and myself, with no other absolute proof whether it was a tubal or abdominal life, Dr. Reamy strongly inclining to the latter; the advanced state of gestation seemingly losing all claims to any probability of a tubal domain.

By this time the lady was in the eighth month of gravidity, and with no hope of surviving the dreadful ordeal, was preparing for a sure death, in spite of our trying to pacify her by citing many similar successful cases.

December 24. I was called, she experiencing some pains, and what did not the examination reveal? The entire fœtus descended into the womb! Mrs. D. almost cried of joy when I announced the great possibility of a natural labor in a few days, though she thought the time was not so near yet.

December 26, at one o'clock a. m., being hastily summoned, I found my patient in lively labor pains, though the organs did not seem to dilate. In a short time, however, I succeeded in arousing the uterus to welcome contractions, and in about one hour and a quarter a nine-pound girl began to cry and kick in the outer world.

The mother claims this to have been her easiest confinement.

Quite a severe inflammation of the uterus scared me the following day, the organ swelling to an enormous size; but a few doses of quinia and a carbolic acid wash turned it all right again, and now mother and child are enjoying a brilliant health.

Diagnosis of Cancer of the Uterus.

In the *Brit. Med. Jour.*, Dr. H. Handford reports the following interesting case:

M. T., aged twenty-four years, was admitted into the Nottingham General Hospital under my care on April 7, 1885. Her family history was good. Menstruation commenced at the age of twelve; the flow lasted four days, and recurred every month. She was married at fifteen, and had had two children, both of whom died before they were six months old. Since then she had two miscarriages at about the third month; the last five years ago, since which time she had been regular. She first noticed a fœtid vaginal discharge about six weeks before admission, and a little later saw Dr. Truman at the Nottingham General Dispensary, who diagnosed cancer of the womb. She never had any rash on the skin or falling out of the hair, and had no syphilitic eruption. On vaginal examination, the cervix was found indurated, enlarged, ragged, and excavated so as to admit the index-finger for about three-fourths of an inch. The uterus was somewhat restricted in movement, but the fundus was not enlarged. The patient was also seen by Mr. Wright, the senior surgeon, who confirmed the diagnosis of cancer. The examination caused a little hemorrhage. I removed a small fragment of the growth, which, upon microscopic examination, was found to consist chiefly of large round cells, with a single large nucleus, but no flat or irregularly-shaped cells. The tissue was pervaded by the mycelium of a filamentous fungus (one of the hyphomycetes).

The patient left the hospital, and died eighteen weeks later, six months from the first symptoms. No post-mortem examination was made.

The diagnosis was between cancer, sarcoma, and syphilis. The ravages of the latter may be very extensive, but are stated to be limited to primary ulcers taking on a phagedænic character. There was no evidence of syphilis in this case. Sarcoma is said almost invariably to take its origin from the lining membrane of the body of the uterus, and not to commence in the cervix. The microscopic examination of the portion removed did not suffice to determine the exact nature of the growth. The fragment was necessarily small, was infiltrated with inflammatory materials, and consisted in large part of vascular granulations. These latter cover the surface of ulcerating new growths, are an important source of the hemorrhage, and, in many cases, differ very little in structure from healthy granulation-tissue; though, in others, "cell-nests," or other characteristic structures, may be found. For these reasons, I have come to the conclusion, after many trials, that negative results of the microscopic examination of scrapings or small fragments by no means disprove the malignant nature of the growth.

Cancer of the Lung.

Dr. A. T. H. Waters thus writes in the *Brit. Med. Jour.*, Feb. 20:

James C., aged 44, was admitted into the

infirmary under my care on January 13th last. He complained of tightness in the chest and slight dyspnœa, but no pain. His illness began, he said, about three months before his admission, and he had been gradually wasting since then. He had, however, followed his work in an iron foundry up to six weeks before coming to us. On examination, we found the whole of the right side of the chest dull on percussion, with very impaired movement. The dulness was very marked, but it did not extend beyond the median line in front. Vocal fremitus was very slight. The breath-sounds were very faint all over the lung. On the left side the resonance was good, and the breath-sounds loud, but healthy. The heart was not displaced, and the sounds were normal. The aspect of the patient, although somewhat pale and sallow, was not otherwise unhealthy. The pulse was 85. On the day after admission, the right pleura was tapped, and twenty ounces of a dark-colored fluid were drawn off by the aspirator. The fluid was very fibrinous, and coagulated soon after it was drawn from the chest; indeed, it coagulated in the canula during the operation. There was a slight improvement in the physical signs after tapping; the breath-sounds were more audible, but the patient did not improve. On January 17th, tapping was again practiced, but only two ounces of fluid withdrawn. The man now became rapidly weaker, and took his food badly. He complained of restlessness and insomnia, but there was no pain. The physical signs in the lungs remained unchanged. There was some expectoration of frothy, tenacious, and rust-colored sputa, for a few days rather abundant. The symptoms of exhaustion gradually increased. The chest was punctured again on the 25th, but only a very small quantity of blood-stained fluid was withdrawn. About February 1st the abdomen began to swell, but there was little or no pain. During the whole time the patient was under observation, his motions were very pale, but there was no jaundice. He died on February 7th.

An Anomalous Case of Renal Calculus.

Dr. James Oliver thus writes in the *Brit. Med. Jour.:*

Calculi may exist for a long time, not only in the pelvis, but in the structure of the kidney, without producing any definite manifestation of their presence; and often they are discovered, on post-mortem examination, in cases in which they were wholly unsuspected during life. Some months ago a young lady, aged twenty-four, consulted me, complaining of aching pain in the right lumbar region, from which she had suffered more or less for six years. During the last two years she had been subject to paroxysmal attacks of severe pain in the same region, shooting across the abdomen towards the left groin, associated with vomiting and occasional rigors. Simultaneously with the recurrence of these attacks of pain, appears a swelling in the situation of the right kidney. For four or five hours prior to the paroxysm, the patient usually experienced an aching in the front of both thighs, but especially the right. On three separate occasions I had the opportunity of examining the patient whilst thus suffering. A cystic swelling, about the size of a small cocoanut, was distinctly felt in the region of the right kidney, the lower and inner margin of which was always more or less sharply defined. It could be readily palpated by the fingers, employed in the manner usual to elicit any change in the renal organ, but was manifestly tender to the touch. There was marked increase of the area of normal kidney dullness, whilst, anteriorly, there was a limited though appreciable area of resonance between the liver dullness and that over the fluctuating tumor. As soon as the paroxysmal pain ceased, which it usually did in twenty-four or thirty-six hours, the swelling gradually disappeared, and the patient was again able to get about as usual. Twelve hours after the cessation of the attack, the right kidney could be felt, apparently normal in size, and no trace of the swelling could be detected. As the tumor disappears, there is no appreciable change in the amount of urine passed. The urine is acid and somewhat thick; it contains a few apparently inflammatory corpuscles, and spindle-celled flat epithelium, with no trace of degeneration; a fact strongly in favor of the supposition of the presence of a calculus, and the removal of the epithelium from the pelvis to the kidney by attrition.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——In a paper on the influence of the sex of the fetus on the length of the intergestation period, Dr. J. Stockton-Hough reaches among other interesting inferences the con-

clusion that under the influence of feebleness, degeneracy and disease, each sex tends to produce a larger proportion of offspring of its own sex.

——Some cases of affections of the eye dependent on hysteria are reported in a reprint by Dr. M. Landesberg. They are of an instructive character.

BOOK NOTICES.

Handbook for the Instruction of Attendants on the Insane. 8vo. Pp. 187. Price, $1.25. Cupples, Upham & Co., Boston.

The Medico-Psychological Association of Glasgow at one of its recent meetings appointed a committee to prepare a short series of instructions for the nurses and attendants in asylums for the insane. The present volume is the result. As expressed in the preface, its object is to give this class of readers such simple notions of the body and mind in health and disease, such instructions for the management of those maladies with which they are usually brought in contact, and such rules for their guidance in matters of every-day experience, as will enable them to do their work with greater intelligence and watchfulness. These ends are closely kept in view, and are well carried out throughout the pages of the volume, and hence it will be found to be one highly useful in establishments for the care of mental diseases.

Transactions of the American Gynecological Society. Vol. 10. For the year 1885. Pp. 356. D. Appleton & Co., New York, 1886.

These Transactions continue to appear in as handsome form and as replete with valuable essays as ever. Of the writers and topics in the number before us we may mention the papers by Dr. Busey on the Natural Hygiene of Child-bearing Life; Puerperal Diphtheria, by Dr. Garrigues; Protection of the Perineum During Parturition, by Dr. Reamy; On a Modification of Emmet's Cervix Operation, by Dr. Sutton; Inflammation of the Parotid Glands after Ovariotomy, by Dr. Goodell; Peristalsis of the Genital Tract, by Dr. Chadwick; The Advantages of the Genu-pectoral Posture in the Vomiting of Pregnancy, by Dr. Campbell; and this does not exhaust the list of those of marked merit. The address of the President, Dr. William T. Howard, is descriptive of two rare cases in abdominal surgery. The minutes, constitution, etc., complete the volume.

Lectures on Dietetics and Dyspepsia, By Sir William Roberts, M. D., F. R. S., etc. Second edition. Pp. 92. From G. P. Putnam's Sons, New York.

These lectures are interesting as being largely the result of original observations and experiment. The theories built upon the facts are also novel and striking, and well merit the attentive consideration of those who would study the digestive functions.

The general headings will serve to indicate the range of topics considered. Beginning with dietetics in general, the author treats of the effect of food accessories on salivary digestion, on peptic digestion, and on pancreatic digestion, and closes with a discourse on the acid dyspepsia of healthy persons. By food accessories he means alcoholic beverages, beef-tea, coffee, tea, sugar, salt, etc. His conclusions are carefully stated and of practical importance.

A Manual of Surgery. In Treatises by Various Authors. In three volumes, edited by Frederick Treves, F. R. C. S., Surgeon to and Lecturer on Anatomy at the London. Hospital. Vol. I., General Surgical Affections, the Blood-vessels, the Nerves, the Skin. Vol. II., the Thorax, the Organs of Digestion, the Genito-Urinary Organs. Vol. III., the Organs of Locomotion and of Special Sense, the Respiratory Passages, the Head, the Spine. Duodecimos, 1866 pages, 213 engravings. Per volume, cloth, $2. Philadelphia, Lea Brothers & Co., 1886.

Surgical Diseases of the Kidney. By Henry Morris, M. A., M. B., F. R. C. S., Surgeon to and Lecturer on Surgery at the Middlesex Hospital, London. 12mo., 555 pages, with 6 chromo-lithographic plates and 40 engravings. Cloth, $2.25. Philadelphia, Lea Brothers & Co., 1886.

The Surgical Diseases of Children. By Edmund Owen, M. B., F. R. C. S., Surgeon to the Hospital for Sick Children, Great Ormond Street, London. 12mo., 585 pages, with 4 chromo-lithographic plates and 85 engravings. Cloth, $2. Philadelphia, Lea Brothers & Co., 1886.

The work whose titles are given above belongs to the "Clinical Manuals for Practitioners and Students of Medicine," the series of which we have already had occasion to mention with praise. These latest publications continue the high character of the previous issues, and will be found to be as comprehensive and as well-prepared as any works of their size which can be named.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

THE AMERICAN MEDICAL ASSOCIATION.

It is simply wonderful with what pertinacity our esteemed contemporary, the *Medical Record*, continues to view the existing professional unpleasantness through partial eyeglasses. In its issue of May 15 it says:

"A PERMANENT SPLIT IN THE AMERICAN MEDICAL ASSOCIATION.

"Now that the American Medical Association has finished its session, and its members have dispersed to their homes, there must come to all a period of calm reflection. Such reflection can hardly fail to show that the Association has committed another serious error, and one from which it will not soon recover. We refer to the arbitrary refusal to admit the Philadelphia delegation. This delegation was the only one sent by the Philadelphia County Medical Society, it was duly accredited, and its rejection was a piece of injustice and folly so monumental as to make one wonder if the gods had not infused some mad frenzy into the minds of the Judicial Council. The immediate result of this act will be to alienate the profession of Philadelphia from the Association, and the sympathies of a very large majority of the profession not attached by political ties to the Association will go with them.

"For it is again demonstrated that the American Medical Association has fallen into the hands of political managers whose unskilfulness and stupidity are so astounding that we feel inclined to commiserate more than condemn.

"No doubt the American Medical Association believes that it can get along quite well enough without the coöperation of the leading physicians of Philadelphia, New York, Boston, and Baltimore, etc.; but without them it can no longer call itself a national or representative body.

"The American Medical Association will continue to live, and we trust will thrive; but it is permanently divided, and will, we fear, never again represent the whole American profession."

It is hardly fair or correct to speak of a *split*, when only a *few fibres* are carried away; it would be more correct to say a *shave*, or a *scrape*. The main body of the American Medical Association is to-day more united than it ever was, and it has lost the allegiance only of those who "got mad" because they could not control. We cannot help but see that the action of the Judicial Council was eminently proper in the case of the *alleged* delegation from the Philadelphia County Medical Society. There were two

sets of delegates before them; one set had been regularly and legally *nominated*, but they were not *elected;* the other set had been elected, but, and this is a big BUT, they had not been legally nominated, and as such nomination is, according to the constitution and by-laws of the Society, a *sine qua non* of a *legal* election, every unbiased mind must hold that they were not *legally* elected. Hence the clear position, which we foreshadowed in our issue of March 27, was that the Philadelphia County Medical Society had no legally-accredited delegates, and that the Society was not entitled to recognition. Like the famous "Kilkenny cats," our representatives have torn themselves to pieces.

The "whole row" from beginning to end has been made by a few men, who, as we have before said, were willing to try to ruin that which they could not control. We have great respect for these few men, among whom are to be found some of the greatest men in our profession, but we cannot have respect for or sympathy with their revolutionary methods of obtaining control. We have been asked by those who questioned our oft-repeated statement of the absolute supremacy of the American Medical Association, whether we would consider it right, *no matter what it did*, and we have answered, and we do still answer unhesitatingly, *yes*. In all bodies where the majority rules, the majority must be right; the right of the majority to rule the minority is the basis of all good government, and when the minority revolt, forcibly, against the majority, they are rebels, revolutionists, and anarchists. If successful, as we were in '76, they are heroes, but none the less they are rebels, simply because they rebel.

The *Medical Record* gives us the side of the *specialist:* let us turn to the other side, and we will present it in the words of a correspondent from Arkansas. He says: "I could not help feeling sorry for the Roberts-Agnew delegation from Philadelphia, at the meeting of the A. M. A. at St. Louis—they were so mercilessly sat down upon by the Association, and most justly so. The specialists, in my judgment, *who* have been raising such a *professional* muss, have to make up their minds to 'eat crow,' or, like Othello, their occupation will be gone; for they are dependent for their business, to a very large extent, upon the 'general practitioner' or 'family physician,' and in their present attitude to organized medicine they cannot expect to receive recognition from the *rank and file* of the profession. As we have before remarked, 'a word to the wise is sufficient.'"

CEREBELLAR SOFTENING.

While we are getting acquainted more and more with the localized functions of the brain, our knowledge of the special functions of the cerebellum is still rather confused. This is probably due partly to the fact that so many conducting fibres enter the cerebellum, and that lesions strictly limited to one part of it or to the whole are but seldom met with. In this respect, therefore, the following case of Dr. Thierry, in Paris (*Progres Med.*, 11, 1886), is of great interest to neurologists.

The patient, æt. 31, is said to have always enjoyed good health until last year, when he suffered from an attack of inflammatory rheumatism. Abuse of tobacco or in venery had not occurred. About a month previous to his admission to the hospital the present disease developed. The first symptoms were violent headache, greenish vomiting, at first but seldom, later several times daily, and attacks of loss of consciousness, amounting more to stupor. The latter were followed by obscure vision and a remarkable weakness of the left side, causing the patient to walk like a drunkard. Sometimes he had to sit down to prevent himself from falling, and occasionally while working at his trade (shoemaker) he dropped down unconscious, dazed. Real apopletic attacks did not occur, neither had he convulsions.

State on Admission.—Complains of great weakness all over left side. He cannot stand erect, must always lie on his right side. There is no paralysis, but the muscles of the left side move sluggishly. The left hand can be opened but partially. Has the appearance of a claw, as in progressive muscular atrophy, though no atrophy is present. No contraction, no convulsive twitchings, no disturbance of motion on right side. Sensation and reflex excitability slightly diminished on left side, otherwise normal. No lesion of skin anywhere. Continuous intense pain felt all over the head. Tinnitus and great impairment of hearing in left ear. Amblyopia and extreme dilatation of pupil on same side. Apathy, continuous somnolency, hallucinations, and speaking incoherently, as in a dream. No excitement; if accosted loudly and shaken, patient replies intelligently to questions. Temperature, 36.3°; pulse, 50, not intermitting; heart-sounds normal; respiration regular, 16 inspirations per minute. In the evening twice vomiting.

Treatment.—Thirty-six grains potassium iodide per diem. From February 24 to 26 no special change. The scanty urine con-

tains neither albumen nor sugar. February 27, patient becomes comatose and cyanotic. The pupil, which had thus far been widely dilated, contracts, and the right remains in that state. At ten o'clock in the morning exitus letalis.

Autopsy.—Internal organs evince no morbid alteration. Cerebrum: Meninges free from adhesions; no trace of inflammation or of miliary granulations. The vessels of the pia seem almost to burst with dark blood, and appear very prominent. In the ventricles large quantity of a clear serous fluid. Very superficial softening of the walls of the right lateral ventricle; the cerebrum has preserved its normal consistence and shows no lesion. Cerebellum: Softening of the left cerebellar hemisphere throughout; its anterior and posterior parts form a grayish white band. Only the parts forming the foot of the peduncle have alone remained intact. At the anterior end of the right hemisphere another superficial focus of softening is found. The middle lobe, the bulbus and the pons are normal. While the basilar artery shows no obstruction, a coagulum closes for a length of about half an inch the left inferior cerebellar artery derived from the basilar. Prof. Cornil made a miscroscopical examination and discovered many granule-cells in the softened portions.

Notes and Comments.

Some Points in the Practice of Artificial Respiration in Cases of Stillbirth, and of Apparent Death after Tracheotomy.

Mr. Francis Henry Champneys, in an article in the April number of the *American Journal of Medical Sciences*, in which this whole subject is carefully considered, thus sums up the treatment:

Never hurry; it is not a question of seconds, and success depends upon a fine exercise of the judgment. Make a good diagnosis, first as to life or death, secondly as to the stage of asphyxia (if life is not extinct). If the child is macerated, it is obviously dead and past hope. If the heart beats, ever so slowly and feebly, it is not dead. If the heart is not beating, death is not certain, unless it can be proved to be inactive for some time. If the child is livid and not flabby, it will probably come round: wipe out its mouth and pharynx, and rub it with a soft cloth down the spine; press gently on the cardiac region. If this produces no effect, inflate the lungs by the mouth, and then by Silvester's method. If air enters the lungs, well and good; if not, try Schultze's method, or insert a catheter. On the first sign of muscular action, plunge the child into cold water, or into alternate hot and cold baths. Vary the treatment between occasional inflation of the lungs, artificial respiration, pressure over the cardiac region, baths, irritation down the spine, according to the judgment; remembering what may be expected of each method, and that no one will suffice for all cases. Watch for signs of resuscitation, namely, improvement in the color, in movements, in cardiac pulsations, as described above. Never be content until the child breathes regularly, and appears to be continually improving.

Chronic Rheumatic Arthritis of the Hip-joint.

In a paper thus entitled, read on March 4, before the Harveian Society of London, Mr. W. Adams contrasted as follows the symptoms of rheumatic arthritis and those of Charcot's disease:

Rheumatic Arthritis.	*Charcot's Disease.*
1. Changes chiefly hypertrophic.	1. Changes chiefly atrophic.
2. Commences in the soft tissue.	2. Commences in the bones.
3. Painful throughout its course.	3. Generally painless.
4. Pain confined to the joint.	4. Pains shoot through the limbs.
5. No febrile disturbance. No gastric or ocular symptoms.	5. All these are present.
6. Reflex symptoms present.	6. Reflex symptoms absent.
7. Limited mobility.	7. Flail-like mobility.
8. Progress slow and chronic.	8. Progress rapid and acute.
9. Patients often reach old age.	9. Patients seldom reach old age.

The Treatment of Intestinal Obstruction by Laparotomy.

Dr. Randolph Winslow reports, in the April number of *The American Journal of the Medical Sciences*, a case of acute intestinal obstruction successfully treated by laparotomy. In commenting on the treatment, Dr. Winslow expresses his opinion decidedly against any and all severe methods of attempting to overcome the obstruction, whether by rough manipulations, or by rectal injections under strong pressure. On the other hand, he deprecates resorting to operation until a fair trial of medical means has failed to relieve the condition, and until it is reasonably certain that there is some mechanical hindrance to the passage of the fæces, which will terminate fatally unless relieved by operation. For obstruction in the large intestine, colotomy would in many cases afford relief. For persistent obstruction of the small intestine, his preference is decidedly in favor of laparotomy in the linea alba below the umbilicus, under rigid

antiseptic precautions, as being the most precise, scientific, and rational means of discovering the cause and seat of trouble, and of remedying it at the same time. Whilst not underrating the risks of laparotomy, he does not think an exploratory incision to be a more serious procedure than abdominal taxis, or enemata under heavy pressure, and he thinks it much more certain and reliable in its results.

News and Miscellany.

American Medical Association.

(*Concluded from page* 637.)

The report of the Standing Committee on

METEOROLOGICAL CONDITIONS,

and their Relations to the Prevalence of Diseases, in coöperation with the British Medical Association, was presented by Dr. N. S. Davis, of Illinois. He stated that the progress of the work had been aided by the U. S. Signal Service, and that sufficient material had accumulated to present an elaborate report, but that it was deemed best to withhold it until the progeess of the cholera epidemic in Europe was better known. The report was adopted.

THE COMMITTEE ON NOMINATIONS

presented the following report of nominations for officers for the ensuing year:

President—E. H. Gregory, M. D., of St. Louis.

Vice-Presidents—Drs. B. H. Miller, of Stillwater, Michigan; W. B. Welch, of Fayetteville, Arkansas; Wm. H. Pancoast, of Philadelphia; W. C. Wile, of Sandy Hook, Connecticut.

Permanent Secretary—W. B. Atkinson, M. D., of Philadelphia.

Assistant Secretary—J. Nevins Hyde, M. D., of Chicago.

Treasurer—R. J. Dunglison, M. D., of Philadelphia.

Librarian—C. H. A. Kleinschmidt, M. D., of Washington, D. C.

Section of Practice of Medicine—Drs. J. S. Lynch, of Baltimore, Chairman; J. B. Marvin, of Kentucky, Secretary.

Section of Surgery—Drs. H. H. Mudd, of St. Louis, Chairman; J. B. Roberts, of Philadelphia, Secretary.

Section of Obstetrics—Drs. S. M. Johnson, of Kansas, Chairman; W. W. Jaggard, of Illinois, Secretary.

Section of Oral and Dental Surgery—Drs. J. S. Marshall, of Chicago, Chairman; E. S. Talbott, of Chicago, Secretary.

Committee on Necrology—J. M. Toner, M. D., of Washington, Chairman.

Judicial Council—Drs. N. S. Davis, of Illinois; Hawkins Brown, of Kentucky; William Brodie, of Michigan; D. J. Roberts, of Tennessee; R. C. Moore, of Nebraska; T. A. Foster, of Maine; James A. Gray, of Georgia.

Trustees of Journal—Drs. P. O. Hooper, of Arkansas; A. Garcelon, of Maine; L. S. McMurtry, of Kentucky.

Time and Place of Next Meeting—Chicago, first Tuesday in June, 1887.

Chairman of Committee of Arrangements—Charles Gilman Smith, M. D., of Chicago.

The report was unanimously adopted.

GENERAL SHERMAN

was then called to the platform, and spoke a few words of compliment and respect. He referred to his own observations of the labors of the surgeons in the late war, and closed by assuring the Association of its cordial welcome to the homes of St. Louis, and expressing approval of such general assemblages of scientific men, which can only result in profit to the public as well as to themselves.

THE ADDRESS ON OPHTHALMOLOGY

was delivered by Dr. Eugene Smith, of Michigan.

Reference was made to the recent discoveries in regard to the action of cocaine, particularly to the occasional toxic action it exerts, and he advised that in all cases it should be tried first in the strength of one per cent., until its action on the patient has been demonstrated, when the strength of the solution employed may be increased to three or four per cent.

He stated that recent experiments had placed the operation of transplanting the conjunctiva of the rabbit upon the human eye, among the recognized operations. Clinical experiences and careful study have demonstrated, that in sympathetic conjunctivitis the inflammation travels along the optic nerve to the unaffected eye. Referring to the use of antiseptics, he stated that they should always be combined with other means for the prevention of suppuration—above all, with careful observation of cleanliness.

Cocaine, he continued, has taken its place in the treatment of painful affections of the ear. A four per cent. solution is usually employed. Bad symptoms have followed its use in but a few cases. The dry treatment of otitis media suppurativa, although strongly advocated by some, has been decided as being applicable to but a certain class of cases,

others improving more rapidly under other methods. The discovery of a causal relation of certain local pathological conditions of the nasal chambers to pulmonary disease, has been an important advance.

The relation of the same diseases to asthma, chorea, and epilepsy, has also been demonstrated by cure by appropriate treatment. Reference was made to the application of electricity to the removal of adventitious tissue from the nasal cavities.

During the year. the intubation of the larynx has been practiced to an extent and with a result that are truly remarkable. It is an operation that bids fair to supplant tracheotomy for the relief of laryngeal affections. Its introduction is due to Dr. O'Dwyer, of New York. Great improvement has also been made in the process of photographing the laryngeal image.

INOCULATION OF YELLOW FEVER.

Dr. Gaston, of Atlanta, Georgia, presented a resolution the purport of which was that, in view of the fact that well-authenticated reports have been received of the successful inoculation with attenuated virus of yellow fever poison, in proof of which Dr. Horace Allen, now present, testifies that he was inoculated and afterward passed through an epidemic of the disease at Rio Janeiro, without contracting the disease, while many others died of it; and in view of the fact that reports have been published which indicate the safety of the procedure, the Association, therefore, petition Congress to appoint a scientific commission and appropriate sufficient funds for an investigation of the method and its success. The resolution was adopted.

A RESIGNATION.

Dr. John B. Roberts, of Philadelphia, offered his resignation of the office of Secretary of the Section on Anatomy and Surgery, in view of the fact that the delegation of the Society of which he was a member had been excluded from the Association. On motion, the resignation was accepted.

EXPUNGED FROM THE MINUTES.

Dr. A. E. Baldwin, of Chicago, then moved that as certain resolutions offered by Dr. Roberts were of a character which cast a reflection on the conduct of our excellent President and Permanent Secretary, therefore that all allusion to said resolutions be expunged from the minutes of the Association. Carried.

Dr. Jackson, of Philadelphia, then read

A PROTEST AGAINST THE ACTION OF THE JUDICIAL COUNCIL

by which the Philadelphia County Medical Society, one of the oldest, most respectable, and the largest of the medical societies in affiliation with this Association, has been excluded from recognition, at this meeting. A motion to table the protest was promptly made and carried.

Dr. N. S. Davis, of Chicago, moved

A VOTE OF THANKS

to the Committee of Arrangements, to all the local officers, and to the people of St. Louis, from whom such cordial courtesies and such kindly treatment had been received. Adopted.

AMENDMENT TO THE BY-LAWS.

Dr. Keller, of Arkansas, offered an amendment repealing that adopted at the present meeting by which the sections nominated their own officers.

Drs. Davis and Johnson were then appointed a committee to introduce

THE PRESIDENT-ELECT,

Dr. Gregory, of St. Louis.

Dr. Gregory accepted the office with a few appropriate remarks expressing sincere gratitude for the honor conferred upon him.

Dr. Brodie, after a few words of thanks to the members of the Association for the manner in which they had supported and aided him in the discharge of his duties, and after congratulating them on the pleasant manner in which all matters on which there existed a difference of opinion had been adjusted, leaving no personal ill-will between any of the members, declared the Association adjourned.

SECTIONS.

In the Section of Obstetrics and Diseases of Children, Dr. H. O. Marcy, of Boston, exhibited on the screen a number of cuts in treating of

THE LESIONS OF THE PERINEUM AND THEIR REPAIR.

These consisted of frozen sections, among others that of a woman who hung herself in the eighth week of pregnancy; another who died during parturition. He showed the bladder and rectum full and empty; the dissection and repair in operations on the perineum; showed Emmet's operation, complimenting his method of dissection; cuts from Hart, Henly, and Savage, and showed cuts of his own manner of operating, which he had reported to this section two years ago. He also showed his "safety-pin," made of heavy German-silver wire.

Dr. E. W. Cushing, of Boston, showed a number of microscopical specimens on the screen in discussing

THE PATHOLOGY OF EROSIONS, SO-CALLED, OF THE OS UTERI.

Dr. A. C. Miller, of Cleveland, O., discussed the paper, and was replied to by Dr. Cushing.

Dr. W. W. Potter, of Buffalo, N. Y., read a paper entitled

SOME OBSERVATIONS ON THE UTERINE SOUND, WITH ESPECIAL REFERENCE TO ITS USE IN GYNECOLOGICAL THERAPEUTICS.

It was but a few years ago when a Ferguson's speculum, caustic-holder, uterine dressing-forceps, and Simpson's sound, were an ample outfit for the practice of gynecology. The sound has been used in almost every malady peculiar to the pelvic organs, and I am sure it is in the range of truth to assert that this instrument has done woman more harm than any other used in the management of her diseases. The young physician is prone to its improper use, and, sad to say, causes often irreparable damage to the genital tract or health of woman. Nor is this animadversion applicable exclusively and alone to the professional novitiate, for many whose experience should have taught them better are guilty of the same. I myself am not holier than thou, but take a full share of blame for past misuse. My experience has taught me in every instance in those cases which seem to invite its use for diagnostic purposes, most earnestly to use it with the utmost caution, circumspection, and gentleness. I would most strenuously insist that this instrument should be applied to only as a *dernier ressort*, and in juncture with extreme doubt. Have we not repeatedly seen endometrium so sensitive as to spring into violent inflammation as a result of contact with the sound? Metritis, both peri- and para-salpingitis, ovaritis, pelvic cellulitis, et id omne, are among the results. What, pray, may all these lead to? Were it possible to group together in one table where woman has been caused to abort by the use of the sound, what would be the array? Those indescribable symptoms, remote and reflex in character, also sympathetic, which we call neuroses—hystero-neuroses if you please, that are difficult to locate but unbearable—neuralgias, headaches, backaches, etc., count up a picture of woe pitiable to think about. Mr. Lawson Tait has found that in his own practice, as experience increases, his use of the speculum and sound grows less and less. This comes from the increased *tactus eruditus*. He says, educate the finger-tips. This were well, but few of us can reach the perfection of a Tait. However, the nearer we can come to attaining this, the better gynecologists we are and the less will we use the sound. The essayist said that the os uteri should always be patulous,and the endometrium free from disease before the sound is used.

When necessary, the delicate virgin-silver probe of Sims is better and safer than the Simpson sound. This should never be passed at the first interview. We should, if possible, avoid it until we are quite familiar with the topography and peculiarities of the sexual tract of our patient. We should wrap absorbent cotton about the instrument to serve as a cushion for the metal. He could not speak in too strong terms against the use of the sound to replace the retroposed uterus. He named this use of the instrument as barbarous practice, and recommended the intelligent and persistent use of manipulation and the genu-pectoral position. The sound has taught us some good things, chief among them being the better use of our fingers. He hoped that with the use of the better educated finger-tips the sound would grow less and less in demand and use, and we shall be rid of much of the opprobrium which the young and growing art, gynecology, is now compelled to suffer.

Dr. Gordon, the President, in a neat speech, complimented the paper very highly, and endorsed every word of it.

Dr. Franklin H. Martin, of Chicago, read a paper on

ELECTROLYSIS IN GYNECOLOGY.

The author first spoke of the theory of action, then described what took place in the normal tissue and in the pathological tissue, or in pathological tissne mixed with normal tissue. He mentioned the principal advocates of electrolysis, and enumerated the diseases in which it was beneficial, viz., varices, polypus, nævi, epilation, hydrocele, bronchocele, extra-uterine pregnancy, hernia, hemorrhoids, epithelioma, and uterine fibroid. He also related his experience with an extra-uterine fibroid. This trouble is reported cured by this means by numerous authors. He gave the particulars of the application of the remedy, spoke of the mixed galvanic and faradic method, and showed his manner of applying electrolysis.

Dr. Ely Vandewarker, of Syracuse, N. Y., complimented the paper, and gave brief expression of his experience. He reported a case of solid uterine outgrowth to which he applied electrolysis. The operation proved to be very painful; the patient groaned and writhed under the pain, though anæsthetized. After eight days he observed a rise in tem-

perature, and an abscess followed. The tumor was reduced in size, but the woman was very ill and barely escaped death. Two other cases have submitted to an operation, but the results have been negative.

Dr. Robert Newman, of New York, took great interest in the subject. He recommended weak currents. Instead of twenty, thirty, or eighty cells, we should use two, three, four, five, or six cells. The object is absorption. The strong current does harm; the weak causes absorption. In gynecology electrolysis has a wide field. The one great thing is, we have a safe and sure remedy to save the woman suffering from extra-uterine pregnancy. Do not use needles, use electrodes. In cases of hardened tissues, electrolysis has done much good, in my experience. In malignant growths and cancers it has done good, and been followed by failure in stricture of the urethra in females. In my hands it has never failed. I hope the gentlemen will not forget to use weak currents.

Dr, Hulbert, of St. Louis, said he was an electrical crank. He had reported some remarkable cures. He said we should measure the dose, as in other remedies, and thought Dr. Vandewarker's failures due to not having measured his dose.

Dr. George Engelmann, of St. Louis, said Dr. Martin had only brought this subject before them in a scientific light. He only touched on the results to be attained. He was surprised at Dr. Vandewarker's and Dr. Newman's speaking so indefinitely of strong and weak currents. He had always insisted on using the galvonometer. Know your dose. Cases had been reported here where cures occurred only after forty-five sittings. If you will measure your electricity, you will cure your patient in five or six sittings of five minutes each. The kind of electricity used is quite as important as the number of cells. Give a sitting of five minutes, and a strength of forty, fifty, eighty, or one hundred milliampères, according to how much the patient can bear; it may cause slight pain at first, but should not after that. Avoid the peritoneum if possible, but if necessary pass it through. He uses one needle and a large plate, fourteen by sixteen inches. The cells are gradually added, until the galvonometer shows enough.

In the Section on Diseases of Children, Dr. Mary Harris Thompson, of Chicago, read a paper on

WHY DISEASES OF CHILDREN SHOULD BE MADE A STUDY BY THEMSELVES.

She said opium and alcohol should in all their forms be discarded as soon as safer remedies could be found, and she was confident it could be done if the subject was more thoroughly studied. The rules for physical diagnosis would not well apply to a child, because they were undeveloped; the child being small and fretful, a correct examination could not be had. Adult remedies were not applicable to a child, even in reduced doses, and it was as important to save the life of a child as an adult.

The discussion was spirited, but the speakers were divided upon the necessity of using opium and alcohol as remedies. Some would not use either in any of their preparations, under any consideration, while a like number felt they could not practice intelligently without either drug in their preparations. Dr. Thompson, in closing, said the application of external heat would often answer the purpose of both drugs, which should be discontinued for moral reasons, if for no other.

From time to time we will furnish abstracts of papers as they come in.

American Climatological Association.

The third annual session of this Association was held in Philadelphia, May 10 and 12, 1886.

The President, Wm. Pepper, M. D., opened the session with an address on

THE CAUSES AND DISTRIBUTION OF CONSUMPTION IN PENNSYLVANIA.

He wished this to be considered simply as a preliminary report. The data obtained, while not sufficient to warrant any positive conclusions, seemed to indicate that consumption is most prevalent in the counties of low altitude, where the rainfall is greatest, and that the number of deaths in proportion gradually diminishes as higher elevations with a smaller rainfall are reached, until when an altitude of 2000 feet is obtained, the death-rate has diminished to less than 1 per 1000.

The city of Philadelphia was separately considered. In a period of twenty-six years it was found that there had been 60,000 deaths out of a total of 400,000, the rate for each year being quite uniform. The rate among negroes is over twice that of the general population. Among the foreign population the death-rate is also in excess of the people at large. Deducting the deaths among negroes and foreigners, the true mortality among the Americans in Philadelphia is much lower than is commonly believed.

The percentage of deaths from consumption as compared with the total number of deaths is by this method nine and a half per cent., as contrasted with fourteen per cent, the rate when all classes are included.

Dr. A. L. Loomis, of New York, then read a paper on

THE EFFECT OF HIGH ALTITUDES ON CARDIAC DISEASE.

In the summer of 1880, while at St. Regis Lake, in the Adirondacks, he was requested to see a gentleman who had just arrived, and was thought to be dying. The patient, aged forty years, was found gasping for breath, cyanosed, with no apparent radial pulse, and bathed with profuse perspiration. Neither heart-sound could be heard. Under the hypodermatic use of digitalis, morphia, and brandy, he improved. The following day it was learned that he had left New York apparently perfectly well. When he reached an elevation of 1,000 feet, his breathing became difficult, and as a higher altitude was reached the difficulty was increased, and was accompanied by cardiac palpitation and a sense of oppression in the epigastrium. When he reached St. Regis Lake, at an elevation of 2,000 feet, he appeared to be dying. Physical examination showed well-marked dilatation of both ventricles, with a loud systolic murmur heard over the præcordia and transmitted a little to the left. At the end of three days he returned to New York. As he reached lower levels, the difficulty of breathing diminished, and when he reached the level he could walk. The irregular heart-action, however, continued, and the feet soon became œdematous, and he died six weeks later with general anasarca and heart insufficiency. No autopsy was made. The patient had never presented any evidence of cardiac disease prior to his trip to the mountains.

Dr. Loomis had seen in all twenty-six similar cases, the histories of five of which were given.

In all cases coming under his observation, the ventricular dilatation was unquestionably the cause of the sudden development of distressing symptoms, and the commencement or the fatal issue seemed to be directly due to the effects on the cardiac circulation of a change from a lower to a higher altitude. The probable explanation of these cases was then considered. He first referred to the nervous supply of the heart. The quality or the atmosphere, which is probably the only operative factor under the circumstances, is the diminished density.

The two important elements leading to permanent cardiac insufficiency are, first, the condition of pulmonary distention consequent upon rarefaction of the atmosphere; and second, the resultant condition of the circulating blood. In the first, the terminations of the vagus are excited by the distention of the lungs; by the excitation of these afferent fibres the cardiac walls and inhibitory gangila of the medulla are paralyzed or weakened. The inhibitory control being lost, the diastolic intervals are shorter and the rhythm increases, but the amount or work accomplished is not proportionate to the visible cardiac energy. The change in the blood, which acts as an important and ultimately the principal factor in producing the cardiac insufficiency, is the deficiency in oxygen. The vaso-motor centres, influenced by the want of oxygen in the blood-supply, excite a general contraction of the arterioles of the body, filling the veins, and affording a large heart-supply, while the arterial pressure rapidly rises as the peripheral resistance is increased. Ordinarily, the heart would relieve itself by excitation of the cardio- and vaso-inhibitory centres, but these centres are held in abeyance by the condition of the blood circulating in the medulla. This increase in the intracranial pressure cannot continue, and sooner or later the heart passes into a state of diastolic relaxation, which is the primary step of a condition of ventricular dilatation. It is not improbable that the blood heavily laden with carbon dioxide, also acts as a disturbing factor of the normal action of the heart through this same afferent mechanism.

If the explanation of the effects of high altitude upon the cardiac circulation be accepted, the risk which one with even slight cardiac insufficiency runs by passing from a lower to a higher altitude is certainly very great; and if the insufficiency is extensive, such changes become immediately dangerous. It must be remembered that cardiac insufficiency may exist in those who give no evidence of it.

Clinically, he relied upon what is termed the muscular element of the first sound of the heart in determining the condition of the muscle walls. The absence of the muscular element of the first sound indicates a failure in the integrity of the heart power, which would lead him to caution such a one against passing rapidly from a lower to a higher altitude. Clinical experience had also convinced him that it was unsafe for one to make such change whose cardiac rhythm was greatly disturbed by nervous excitement by rapidly ascending a long flight of stairs.

Dr. Frank Donaldson, jr., of Baltimore, then read

A PRELIMINARY ACCOUNT IN REGARD TO CIRCULATORY AND RESPIRATORY CHANGES OBSERVED IN ANIMALS PLACED IN THE PNEUMATIC CABINET.

The experiments had been performed by Prof. H. N. Martin, of the Johns Hopkins University, and the writer. The animals employed were rabbits, which had been chloralized. It was found—

1. When the animal is breathing air from outside of the cabinet, rarefaction of air within the cabinet causes a marked fall of general arterial pressure, but has no influence on the pulse-rate. The fall of pressure lasts only a short time (ten or twenty seconds), and is often followed by a temporary rise above the normal.

2. This fall of systemic arterial pressure depends on two factors: greater flow of blood to the skin when the air around the animal is rarefied, and greater accumulation of blood in the lungs when they are distended.

3. Of these two factors, accumulation of blood in the lungs is the more effective; for if the animal breathes air from the cabinet, and not from the outside, rarefaction of the air within the cabinet (in this case accompanied by no special expansion of the thorax) has but a trivial effect in lowering arterial pressure.

4. When the animal is breathing external air, rarefaction of the air within the cabinet usually has no effect upon the respiratory rate nor upon the extent of individual respiratory acts, unless the fall of blood-pressure be considerable. If it be considerable, symptoms of anæmia of the medulla oblongata show themselves. In some cases there is more forcible dyspnœic breathing, and in some, dyspnœic convulsions similar to those which occur when an animal is bled to death, and due to the same cause, viz., deficient blood flowing through the respiratory centre.

5. The rapid recovery of general arterial pressure, while the animal is still in a rarefied atmosphere, but breathing external air, is probably due to excitation of the vasomotor centre, which, as is well known, is excited whenever the blood-supply is defective.

6. The brain, enclosed in a rigid box which is practically unaffected by variations in the atmospheric pressure, has its circulation more disturbed in the pneumatic cabinet than any other organ, with the exception of the lungs.

7. Compression of the air within the cabinet while the lungs are in communication with the external air, causes a considerable transient rise of blood pressure. This is probably mainly due to the forcing of the blood from the cutaneous vessels, but there has not yet been sufficient time to investigate this point thoroughly.

8. Compression of the air within the cabinet while the lungs are in communication with the external air, slows the pulse as the arterial pressure rises. This is probably due to excitation of the cardio-inhibitory centre by increased intracranial blood-pressure. Further experiments are, however, necessary before this can be positively stated.

9. In certain cases when the air within the cabinet is rarefied and the animal is breathing external air, the respiratory movements cease altogether for several seconds. As to the cause of this physiological apnœa, we are not yet ready to form an opinion. It may be due to extra accumulation of air in the alveoli of the lung, or to distention of the lungs, exciting those fibres of the pneumogastric which tend to check inspiration.

These papers were discussed by Drs. Pepper, Bruen, and Hudson.

Evening Session.

The first paper of the evening was entitled

A CLINICAL REPORT OF CASES TREATED BY PNEUMATIC DIFFERENTIATION,

by Dr. H. F. Williams, of Brooklyn.

The reading of the paper was preceded by a demonstration of the cabinet, showing the different methods of application of the apparatus. The speaker reported forty-five cases in which the cabinet had been employed, and described sixteen cases in detail.

Dr. V. Y. Bowditch, of Boston, then followed with a paper on

TEN MONTHS' EXPERIENCE WITH PNEUMATIC DIFFERENTIATION.

He gave the clinical results of the treatment of twenty-seven cases since June 30, 1885. Pulmonary phthisis, in its tubercular and non-tubercular forms; bronchitis, in its acute and chronic forms, with and without emphysema or asthma; and retraction of the lung from long-standing pleuritic effusion, were the diseases which he had treated in the pneumatic cabinet. His experience was such that, although he had been unable to accomplish thus far such brilliant results as some others had claimed, yet he felt convinced of the very marked beneficial effect of the cabinet in many cases where other means had failed to give relief, and of its curative power in one case of incipient tubercular trouble, and he looked forward

with hope to what may be done in the future with this new method of treatment.

THE PHYSICS AND PHYSIOLOGICAL ACTION OF PNEUMATIC DIFFERENTIATION.

Dr. J. H. Platt, of Brooklyn, said he believed that the effect of reduced air-pressure upon the periphery of the body is to increase the expansion of the thorax in inspiration, and to diminish its contraction in expiration, consequently to increase the amount of residual air. By the increased pressure in the lungs it will tend to exsanguinate them, and to raise the arterial blood-pressure in the general circulation. He believed that such benefit as results from the use of the cabinet is due mainly to the reduction of congestion in the lungs by the air-pressure within them, and by the increased expansion and movement of the lungs favoring their greater action, and modifying their nutrition.

The President, in calling for discussion upon the preceding papers, referred to the apparatus of Waldenberg, and the neglect of any reference to this method of treatment in most papers on pneumatic differentiation. The use of this apparatus with proper hygienic and dietetic restrictions, is so gratifying that it cannot be forgotten in a discussion of this kind. It must be remembered that this plan of treatment is simply an adjuvant to hygienic and dietetic treatment.

Dr. Loomis, of New York, considered that the most useful application of the pneumatic cabinet was in pulmonary gymnastics. He had never seen any evidence that sprays or vapors reached the lungs, and he had never seen any effect on the bacilli from these.

There are certain cases of phthisis which always present a sluggish circulation of the periphery, and which pass rapidly from one stage of the disease to another. In these cases the use of the cabinet in the Sanitarium in the Adirondacks had an exceedingly favorable influence upon the capillary and general circulation, while the pulmonary lesions remained without change. Such patients have gained in weight and flesh. The use of the instrument is not to be confined to pulmonary disease. In anæmia and nervous diseases, with feeble circulation, the apparatus may be found of benefit.

Dr. J. Solis Cohen, of Philadelphia, thought that the results recorded from the use of this apparatus were no better than those obtained by older and simpler forms of apparatus. He reported patients in advanced stages of phthisis whose lives had been prolonged ten years by the use of the Waldenberg apparatus. He agreed that the principal advantage was from the pulmonary gymnastics.

TUESDAY, MAY 12.—SECOND DAY.

Morning Session.

The report of the Committee on Health Resorts was received and ordered printed in the proceedings.

Dr. Roland G. Curtin, of Philadelphia, then read a paper on

ROCKY MOUNTAIN FEVER.

From his own experience and from correspondence with residents in Colorado, he concluded that Rocky Mountain fever is not a specific fever. Under this head he thought that probably there had been classed cases of typhoid fever, typho-malarial fever, and ordinary continued fever. In these altitudes, these diseases are undoubtedly largely modified by the conditions present. The various influences which might tend to alter the aspect of the diseases were then referred to.

Dr. E. W. Schauffler, of Kansas City, confirmed this opinion.

Dr. C. C. Rice, of New York, then spoke of

HOW THE THERAPEUTIC VALUE OF OUR MINERAL SPRINGS MAY BE INCREASED,

and presented the following conclusions:

1. Physicians should make a careful analysis of our mineral springs.

2. The medicinal value of the waters should be tested by clinical investigation, and the conclusions published for the benefit of the profession.

3. If the waters are found to present marked merit, the physician should interest himself in developing the springs, improving the baths, etc.

4. Physicians, in sending patients to the springs, should be more careful to select the proper water, and should send with the patient the diagnosis and history of the condition, for the benefit of the physicians at the bath.

5. The patient, while at the mineral spring, should be under a more rigid medical discipline.

The discussion of this paper was participated in by Drs. Bruen, van Bibber, and Kretschman.

Dr. Didama, of Syracuse, read a paper on the

CLIMATE OF MEXICO.

The paper was based upon somewhat conflicting communications from physicians practicing in Mexico.

Dr. Edward T. Bruen, of Philadelphia, followed with a paper on

THE SOUTHERN ADIRONDACKS,

describing his experience in this locality, giving the results of meteorological observations, and describing the classes of patients likely to be benefited by a sojourn in these regions.

Dr. E. A. Schauffler, of Kansas City, then spoke of

THE CLIMATE OF EL PASO, TEXAS.

El Paso is 340 miles south of Santa Fe, and is 3700 feet above the sea level. The soil is sandy and porous. The great advantages of this climate are the mild winter and the small rainfall. The annual mean temperature is 61.59°. The winter mean is 47.9°. The average rainfall for several years has been about twelve inches. The winter months are the dryest of the year. The air is exceedingly bracing and tonic.

Dr. A. N. Bell, of New York, read a paper describing

SOUTHERN PINE PARKS,

a new health resort of North Carolina.

Afternoon Session.

The following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—Dr. F. Donaldson, of Baltimore.

Vice-Presidents.—Drs. V. Y. Bowditch, of Boston, and Roland G. Curtin, of Philadelphia.

Secretary and Treasurer.—Dr. J. B. Walker, of Philadelphia.

Additional Member of Council.—Dr. F. C. Shattuck, of Boston.

A communication was received from the Committee of the American Surgical Association, inviting the Society to appoint a committee to confer with like committees from the other special societies in reference to the organization of a

CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

The communication was approved, and the following committee was appointed: Drs. A. L. Loomis, of New York; F. Donaldson, of Baltimore; F. C. Shattuck, of Boston; E. T. Bruen, of Philadelphia; and W. W. Johnston, of Washington.

Dr. H. B. Baker, of Lansing, Mich., then read a paper on

THE CAUSATION OF PNEUMONIA.

The atmospheric condition, he said, which is most closely associated with pneumonia, is the night ozone, but although this is perhaps one factor, it is probably not the controlling force. He believed that the statistics which he presented showed that the causation of the disease is absolutely controlled by the meteorological conditions.

Dr. J. H. Musser, of Philadelphia, then offered some

SUGGESTIONS REGARDING THE PREVENTION OF PHTHISIS IN MILL HANDS.

He showed that states of ill-health are common in this class of artisans, and asserted that it is very largely due to an inadequate supply of food, which is improperly selected and prepared, and to carelessness in attention to digestion. This cause obtained more largely than bad hygienic surroundings, or the occupation itself. If this be true, the remedy is to have the system of the Willimantic Cotton Company used by all mill proprietors. That company has proven by experience and careful calculation that it pays them in quality and quantity of work done to supply milk to their boys and bouillon to their women twice daily, and that the health of the operatives is promoted, and their lives prolonged thereby.

Dr. C. L. Dana, of New York, read a paper on the

INFLUENCE OF HIGH ALTITUDES WITH REFERENCE TO NERVOUS AFFECTIONS.

The observations had been made by physicians at Colorado Springs. The climate seemed to be unfavorable for nervous affections in children, such as chorea. It seemed to be bad for nervous affections in women. High altitudes do not necessarily injure epileptics. In chronic obstinate insomnia in anæmia and malnutrition, the high altitude appears to be beneficial. In chronic affections of the cord the effects seem to be unfavorable.

He thought that the climate tended to produce lithæmia and arthritism, with consequent irritation of the nervous system. The best results are obtained in debility, neurasthenia, and especially in anæmia, insomnia, and melancholia, associated with anæmia and malnutrition.

A vote of thanks was extended the College of Physicians of Philadelphia for the use of its hall, and the Association adjourned *sine die*.

American Surgical Association.

At the seventh annual meeting of this Association, held in Washington, April 28, 29, 30,

and May 1, the following papers were read: "Physiology and Surgery of Motor, Sensory, and Moto-sensory or Compound Nerves," by Dr. Moses Gunn, of Chicago; "Diagnostitial Laparotomy," by Dr. Christopher Johnston, of Baltimore; "Two Cases of Laparotomy," by Dr. J. F. Thompson, of Washington; "A Consideration of the Bacteria of Surgical Diseases," by Dr. Harold C. Ernst, of Jamaica Plains, N. Y.; "A Sterilized Atmosphere," by Dr. David Prince, of Jacksonville, Ill; "The Surgery of the Pancreas as Based upon Experiments and Clinical Researches," by Dr. N. Senn, of Milwaukee; "Two Cases of Cholecystomy," by Dr. Charles T. Parkes, of Chicago; "A Case Simulating Abdominal Pregnancy—Laparotomy, Cæsarian Section, and Removal of a Living Child," by Dr. John S. Coleman, of Augusta; "Traumatic Aneurism of the Internal Carotid Artery," by Dr. T. F. Prewitt, of St. Louis; "Lipoma Testis, or a Large Accumulation of Fat in the Tunica Vaginalis," by Roswell Parke, of Buffalo; "Nephrectomy on a Patient Twenty-three Months Old," by the same author; "Stretching of the Facial Nerve," by Dr. W. W. Keen, of Philadelphia; "Subcutaneaus Division of Urethral Stricture," by Dr. C. H. Mastin, of Mobile.

The President announced the following committee on the proposition looking to the formation of a Congress of American Physicians and Surgeons: Drs. C. H. Mastin, Charles T. Parkes, J. Ford Thompson, J. Ewing Mears, and N. Senn.

The officers elected were as follows:

President—Hunter McGuire, M. D., Richmond, Va.

Vice-Presidents—T. F. Prewitt, M. D., St. Louis, and J. W. Gouley, M. D., New York.

Secretary—J. R. Weist, M. D., Richmond, Ind.

Recorder—J. Ewing Mears, M. D., Philadelphia, Pa.

Treasurer—P. S. Conner, M. D., Cincinnati.

Council—Drs. Hunter McGuire, John S. Billings, L. McLane Tiffany, R. A. Kinloch, and Moses Quinn.

Honorary Members—Foreign, Sir William MacCormac; *American*, Professor Henry J. Bigelow.

Active Members Elected—Drs. H. H. Mudd, St. Louis, and Joseph Ransohoff, Cincinnati.

Time and place of next meeting, the second Wednesday of May, 1887, at Washington.

Adjourned.

The Pennsylvania State Medical Society.

Gentlemen from Philadelphia and vicinity who would attend the Pennsylvania State Medical Society at Williamsport will find great advantage by patronizing the Reading R. R. Co. The train service between Philadelphia and Williamsport is as follows:

Leave Philadelphia 9:50 a. m., 5:50 p. m.; arrive Williamsport 5:50 p. m., 12:40 midnight.

Returning, leave Williamsport 3:00, 10:00 a. m., 12:00 noon; arrive Philadelphia 9:45 a. m., 12:10, 8:50 p. m.

You will notice the trains leaving Philadelphia 9:50 a. m., and 5:50 p. m., and Williamsport 3:00 and 10:00 a. m. are the fastest.

Items.

—*Little Boy*—"Mamma, they call all the Wall street men bulls or bears. Which is papa?"

Mamma—"O dear, Willie, don't ask so many questions; go and ride your velocipede."

Little Boy—"Well, I just want to know whether I am a calf or a cub."

—It is related of a certain judge in a French court of justice, that, on the hearing of a case involving some details of a decidedly nasty character, he appealed to all *honest* women to leave the court. After waiting patiently some few minutes, and seeing that not a lady had stirred, he called to the usher, "Now that all the honest women have left, turn out the others,"

—When a great ruler dies in Europe some one calls in his ear three times. Once is enough in Kentucky. A friend steps reverently to the couch of the deceased and whispers—not necessarily loud—"Let's take a drink." If he makes no reply, then he is dead beyond peradventure, and the funeral is proceeded with.

—The King of Servia has made a proclamation in favor of antisepsis in the following words: "Whereas it is irrefutably proved by science that the so-called antiseptic treatment of wounds yields more beneficial results than all other methods, we are pleased to order that henceforward the said antiseptic plan of treatment be solely employed in all hospitals of our kingdom, and that corrosive sublimate and iodoform be used until our further dispositions." The *Brit. Med. Jour.* explains that this is not taken from *Punch*, as might be expected from its sound, and wonders what Lawson Tait or Keith would do in Servia.

"Pallas Syringe." The most useful Instrument for Vaginal Medication and Irrigation.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to maintain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

RIDGE'S FOOD

FOR INFANTS AND INVALIDS.

Cereal foods are regarded by some with disfavor, as diets for infants, especially by those who maintain the dictum of chemistry in the matter as conclusive. It is urged that as they usually contain a certain amount of unconverted starch, this ingredient, owing to the absence from a baby's saliva of the solvent "*ptyalin*," must cause indigestion and irritation in its passage through the stomach and intestines. Yet Bouchardat and Sandras have demonstrated that starch, given to animals in excess of what the saliva can act upon, has its corpuscles eroded, dissolved, and transformed into sugar, when it meets the pancreatic fluid in the duodenum. The inference is that the conversion of starch is not wholly dependent on the secretions of the buccal cavity, and that the presence of a limited quantity in an infant's food is not necessarily a source of disorder. Moreover, in dietetic questions the verdict of chemistry can only be received *cum grano salis*; and the final appeal is to practical experience; what might, could, would, or should be, under supposed conditions, loses much of its practical value, when we have easy access to what is.

The preëminent popularity of Ridge's Food has caused it to be singled out for special criticism and attack, and unsparing denunciations have been hurled at it by and on behalf of unsuccessful rivals, whose professed zeal for the welfare and protection of the innocent public would be really touching, if it did not employ the language of disappointment and defeat. Our appeal to the public for its patronage has rested on the excellence of our product; and its full justification is found at this time in an experience of thirty years, during which the sales of Ridge's Food, throughout Great Britain and her Colonies, as well as in every State in the Union, have steadily and largely increased.

Ridge's Food is made from carefully selected winter wheat which, having been reduced to an almost uniform fineness, is thoroughly cooked by a steam baking process. The nitrogenous and phosphatic elements, in which wheat is so rich, are carefully preserved, and a large proportion of the starch is converted into dextrine, while the residue undergoes a further change when the food is prepared, as directed, in the nursery, producing an article of diet at once abundantly nutritious and easily digested. Samples of the preparation will be found alittle sweet and slightly alkaline.

It is claimed for Ridge's Food that it is acceptable to the most irritable stomach of infant or invalid, when used (as sometimes it must be) without milk; and that then it is alone sufficiently nutritive to sustain life.

It is also affirmed that the objections urged against the use of cereal foods in no way or degree apply to our preparation; that the consequences predicted as following such a diet for infants never occur where Ridges Food is used. So contrary, indeed, is the prediction to the results of experience, that an eminent firm of druggists in Chicago, who for many years have sold largely of our preparation write: "Its soothing and satisfying properties are so marked, as often to cause customers to inquire *it does not contain some opiate?*"

We shall be pleased to forward a sample of RIDGE'S FOOD to any physician not yet acquainted with it, who may favor us with their address, satisfied that, with a fair trial, we shall secure his commendation.

PUERPERAL FEVER AND THE EARLY EMPLOYMENT OF ANTISEPTIC VAGINAL INJECTIONS.*

BY E. G. ZINKE, M. D.,

Of Cincinnati.

This paper considered chiefly the value and necessity of antiseptic or simply warm water injections as recommended for prophylactic purposes in normal cases of labor in private practice. It dwelt largely, also, upon the differential diagnosis between puerperal septicæmia and remittent fever following parturition. The paper was based upon a case in the doctor's practice, of which the following is a brief report:

Mrs. ———, American, æt. 26, suffered a miscarriage at the end of the eighth calendar month. The labor was entirely normal, as was also gestation, up to the miscarriage. The placenta came away spontaneously, and after only a few moments. The external genitalia were washed, but no antiseptic washes used.

All went well till the third day, when the patient had a chill, followed by a temperature of 106°. She experienced, however, scarcely any pain, and the lochia were free from odor. Two hours later she had another chill and the temperature went up to 107.5°. Prof. Palmer was called in consultation. He thought the high temperature due to something in the uterine cavity, but Dr. Zinke did not think this possible from the nature of the labor. It was determined to await the action of quinine before washing out the uterine cavity. Later, carbolized warm-water injections and turpentine stupes were added to the treatment. Temperature fell to 101°, then rose to 103°. Only slight tenderness in the hypogastric region, and the lochia free from odor. When the temperature reached 104.5°, the uterine cavity was washed out with warm carbolized water, using the reflex uterine catheter. This was followed by some fever, but there was no decline in the temperature, neither was there a removal of anything which might be the cause of the trouble. The temperature fell later under the use of tr. veratrum viridi and salicylate of soda.

Comparing the local manifestations with the range of temperature, the doctor became more and more convinced that the malady was not local in character.

Was it typhoid or remittent fever? Diarrhœa, rose spots, and stupor were absent. The husband then stated that about a month before her confinement she had complained of languor and chilliness. Was it then remittent? In all probability, yes. His consultant did not concur with him. Seventeen days after confinement the temperature was 99.5°. Next day, 101.4°, and still rising. The next day, the doctor's orders not being followed, he retired from the case. Subsequently to this, she was only part of the time under the care of a physician, and no record of the temperature was kept. The patient recovered after a sickness of two months' duration.

The questions which present themselves for consideration are:

1. Was this a case of puerperal septicæmia, remittent fever, or something else?

*Abstract of paper read before the American Medical Association.

2. Could it have been avoided by the early use of antiseptic vaginal injections?

3. To what extent is the use of antiseptics scientifically and practically justifiable or necessary?

The doctor did not believe this to be septic, but if so, thought it to have entered through another channel than the parturient canal. Puerperal fever, he thought, should embrace only those diseases which occur during the puerperal state. He was satisfied that all cases of puerperal fever which find their inception through the obstetric channel from an external cause may, to some extent, be mitigated or prevented by the early and frequent use of antiseptic vaginal injections. Scarlatina, measles, diphtheria, etc., find their way through other avenues, and often mislead the physician.

Antiseptics in normal labor ought not to mean anything except ordinary cleanliness in every respect, the avoidance of frequent examination and unnecessary aids, needless exposure in the support of the perineum, the tying of the cord, the delivery of the placenta, and the washing after labor.

Washing out the vagina immediately after normal labor, he thought, should be termed meddlesome midwifery, did no benefit, prevented nothing, and might do harm. In prolonged or instrumental delivery, if the hand has been introduced, or if injuries have been sustained, vaginal injections are always, uterine injections rarely indicated.

The essayist referred to a death after vaginal injections in the practice of Dr. J. C. Cleveland, of Cincinnati, and to the writings of Drs. Bartlett and Lydston unfavorable to the routine injection.

I admit that many times the fault may lie with the individual who makes these injections. But this charge should not be made general, for surely it does not require a very high degree of education and skillfulness to carry them out properly. Therefore the charges (made by those who apply antiseptic injections in every case, that the trouble arising in certain cases is due to this cause alone,) is certainly not tenable, and seems to me a poor excuse. The ground which I am taking is sufficiently supported by high medical authority, and justifies the conclusion at whichI have arrived.

In conclusion I wish to state that out of nearly 400 labor cases attended by myself, the one just submitted to your consideration is the first that would come under the term puerperal fever (if such it should prove to be in your opinion). I have seen a number of cases of puerperal septicæmia, but none of them were under my care as physician-in-charge during labor. They occurred principally in the hands of midwives, and in a few cases in which I was called in consultation.

In the early part of my professional life, I invariably used antiseptic injections whenever I had the time to make them myself. My practice called me largely among the poorer class of people, who could not pay for a syringe and drugs, and, occasionally, even when able to supply these, they obstinately refused to go to the expense. Speaking from experience, and with a typical kind of good sense, they declared "that it was all nonsense; they had never heard of such a thing before." To my surprise, all these cases, though frequently abnormal and complicated in character, did well, and, I must confess, some even better than those in which antisepsis was rigidly carried out.

Notwithstanding, according to precept, I insisted upon vaginal injections whenever and wherever it was possible. Suddenly, about three years ago, I observed for the first time the ill-effects from the use of a Fountain syringe. Half an hour after the injection, though not the first one nor immediately after termination of labor, pain supervened—and such pain! Whoever has seen a case of uterine colic will know what that means. One grain of morph. sulph. subcutaneously was necessary to subdue this patient's agony. In the course of the same year I had two other similar experiences. The last occurred in a case in which I took particular care that all should be done properly. Everything progressed favorably; the first injections were used on the fourth day after labor. The ill-effects followed as quickly as related in the first case: but the suffering was much more intense. The patient moaned piteously, and with her hands firmly pressed upon the abdomen, she reeled from side to side, crying for help, and exclaiming in heart-rending tones: "My God, what is the matter with me?"

Now, gentlemen, since we may have as a result of carefully employed antiseptic injections such scenes of suffering and even fatal results, is it not uncalled for and wholly unjustifiable to resort to them in normal cases of labor?

—It is said that adding half a teaspoonful of dilute muriatic acid to a pint of water, mixing this with a quart of milk, and then boiling, will produce fine curds as in woman's milk, and will be of pleasant taste.

ECZEMA.*

BY PROF. WILLIAM H. DRAPER, M. D.,

Of New York.

This old man, 69 years of age, is very fat, as you see, and this trouble, which is an eczema of the legs, developed itself first last spring, and he neglected it and went about with a hickory stick, which he still likes to keep in bed with him, and he had to keep constantly scratching his legs. When he came in, his limbs were much distended with an œdematous swelling, and it was thought that this might be the cause of the skin lesion. But an examination of the chest and belly showed no cause for the œdema, and so I am inclined to think that the œdema was secondary to the eruption. At all events resort was had to the oil of cajeput as a local stimulant, and the limbs were bandaged from the toes up to the knees; and this has caused the œdema largely to disappear, and has pretty well restored the skin to a healthy condition. This sort of eruption is not uncommon in old people, and especially if they are afflicted with varicose veins. For the long-continued hyperæmia of the skin thus induced interferes with its nutrition, so that eczematous troubles easily arise, and slight wounds even may cause ulcers upon the limbs. The only way to treat these patients is to put them to bed, and keep the leg in an elevated position and supported by a good bandage or an elastic stocking, and the eczema will get well without much treatment. But oily applications, such as zinc ointment and the like, may also be made, in order to relieve the itching, and so prevent the patient from scratching the parts constantly.

MEDICO-LEGAL NOTES.

BY HENRY A. RILEY, ESQ.,

Of New York.

The New York Legislature has passed a bill appointing a commission to look into the subject of capital punishment, with a view to substituting some other method than hanging. The members of the commission are Elbridge T. Gerry, of New York city; Matthew Hale, of Albany; and Dr. A. P. Southwick, of Buffalo. The first two persons are lawyers, and represent the sentiment of the Medico-Legal Society of New York, which framed a bill some time since having the same object in view.

The bill directs the commission to "investigate and report to the Legislature of the State of New York on or before the fourth Tuesday of January, 1887, the most humane and practical method known to modern science of carrying into effect the sentence of death in capital cases. It is also provided that the report shall be in detail, accompanied by drawings and specifications of any appliance recommended by such commission, together with the cost of construction, maintenance, and probable durability. The bill presented by the Medico-Legal Society to the last Legislature allowed the condemned criminal to choose the form of inflicting the death penalty.

Congress seems likely to pass a very stringent oleomargarine law, for as the House Committee stated in its report, the legislation is demanded by nine-tenths of the people. Measures with as much "politics" as this behind them are pretty certain to become laws.. The principle upon which the bill is based is the right of Congress to impose internal revenue taxes upon manufactured compounds; and although it is not revenue which is wanted, but rather the suppression of the traffic under the guise of taxation, the bill will nevertheless have to depend for its constitutionality upon the taxation theory. The bill imposes a special tax of $600 on manufacturers of oleomargarine, of $480 on wholesale dealers, and $48 on retail tradesmen. If this special tax is not paid, the manufacturer is to be fined from $1,000 to $5,000, the wholesale dealer $500 to $2,000, and retail dealers $50 to $500. Oleomargarine must be packed in firkins, tubs, or other wooden packages, which have not been used before, and they must be marked, stamped, and branded as the Commissioner of Internal Revenue may prescribe. A violation of this provision is punished by a fine of not less than $100 nor more than $1,000, and by imprisonment not less than six months nor more than two years. All oleomargarine manufactured in this country is to pay a tax of ten cents a pound, and the imported article, besides the import duty, is to pay also a tax of ten cents a pound. The removal of the stamps, marks, or brands on any package of oleomargarine is punished by a fine from $100 to $2,000, and by imprisonment of from ten days to six months. All fines, penalties, and forfeitures may be recovered in any court of competent jurisdiction, and one-half is to go to the informer.

The House Committee on Agriculture states that about 200,000,000 pounds of the various imitations of butter are manufac-

*Abstract.

tured each year, and that the dairy interests are seriously threatened by the continuance of the manufacture.

Dr. Thomas S. P. Miller is colored physician residing in New York, and is the examining physician of a colored lodge of Odd Fellows. The secretary of this lodge recently made a charge against Dr. Miller that he was practicing without a license, and was not competent for his profession. The physician thereupon brought suit for libel against the secretary, and the trial has just been concluded by a verdict of six cents damages in favor of the plaintiff.

The crime of robbing graves for purposes of dissection does not seem to have been stopped by the heavy penalties imposed, nor by the fact that the laws permit, under restrictions, the dissection of bodies of unclaimed paupers. The latest instance of the kind is connected with the county almshouse of Wayne county, New York. The robbery has been going on, it is thought, for years, and at least a score of graves have been opened and the bodies found to have been taken away. The account given states that there were twenty-two deaths during 1884 at the almshouse, and of these cases at least twelve bodies were stolen. The thefts were, it is said, an open secret about the almshouse that year, and the inmates terribly frightened by the thought that at their death their bodies might also be carried away for dissection. Who the guilty parties are is not certainly known, but it is generally believed that they are medical students from the towns of Lyons, Phelps, and Newark. An old Lyons physician says that one night after the burial of a pauper who died of a curious disease, eleven medical students from villages within a radius of nine miles met in the cemetery, coming in twos and threes, and each with the intention of stealing the body. It was decided that the body should go to the one drawing a certain number from a hat. The cemetery has furnished medical students with subjects for years, and in 1885 several bodies were dissected in an unused office in Lyons. A large part of the stolen bodies have been shipped from Lyons to medical colleges in New York, Albany, and Buffalo. The bodies were usually put in old oil or whisky barrels and tightly headed in. The price paid in one instance for a body was $30.

The contract system of disposing of prison labor is quite prevalent at the South, notwithstanding the exposures which have been made of its cruelty and excessive mortality. From Kentucky quite recently reports have come which show that for cruelty, starvation, and neglect, the system is as bad as can be found in Siberia even. Some 200 have been employed in working the mines at Greenwood, and of this number some sixty are sick from overwork and poor and insufficient food. It is said that the men see the sun only as they go from the barracks to the mines, in which they work eleven hours. Hard tasks are set them, and a failure is met by a whipping with the "strap" on the bare skin. Terrible tales are told of the horrors arising from its use. One resident of Greenwood frequently hears the helpless victims cry for mercy. The "strap," as used here, is fully equal to the Russian knout. From March 6 to March 13, forty whippings were inflicted wiih it. Not long since, one convict deliberately killed his partner in mining so that he might be taken from the mines and sent to Frankfort, where murderers and other criminals of a high grade are kept, but he was kept at the mines and no attention paid to the act of killing. The contractors make about $40 per month from the labor of each convict, and it is no wonder that they are in favor of the system.

ALBUMINURIA.*

BY JOSEPH T. SMITH, M. D.,

Of Baltimore, Md.,

Visiting Physician to Bay View Asylum,

Few words in our medical vocabulary are in such constant every-day use as albuminuria; at the same time there are possibly none which, from a clinical point of view, give us such a vague idea of the real condition of things; it is a hybrid term signifying "a condition of the urine in which it contains albumen * * *." It is a word used to express the fact that the urine contains albumen, and that of a peculiar kind; but it gives us no idea of the source from which the material comes, nor of the diseased condition or conditions which produce it, if, indeed, it may not exist in the urine from a perfectly healthy body; still more, we cannot say, from the presence of albumen alone, whether the kidneys are at fault, or disease is lurking in remote organs, as the liver or lungs. Failing thus to give us any positive information upon points so vital, the presence of albumen in the urine can be of value only as a symptom, oftentimes only one of many to help us map out the path to a cor-

*Read before the Clinical Society of Maryland, April 2, 1886.

rect diagnosis. Just as we find fever a symptom of inestimable value in pointing out the causes and gravity of certain diseases, so we find in others that albuminuria is an important guide-post to indicate the road; but neither is of much value in and by itself.

Possibly upon no one symptom, unless it be that of fever, has more time and thought been expended than upon albuminuria; it would no doubt be a surprise to all of us could we know how many gallons of alcohol and nitric acid, to say nothing of other chemicals, have been poured forth in search for this otherwise invisible substance in the urine. The journals, in almost every issue, contain one or more articles upon the subject; in the last issue of one of the best, is published an article on ferrocyanic pellets as a means of detecting albumen; indeed, if one looks at the literature upon this one subject to-day, he would think it a something new, so full and voluminous is it, instead of dating back to 1827, or earlier, at which time Dr. Bright thought that in dropsy, with albuminous urine, he had discovered the golden key which would unlock the secret of disease of the kidney, instead of opening up the path to the diagnosis of very many distinct diseased conditions, and these not of the kidneys only, which were but faintly outlined in his mind at the time. From 1827, then, until the present day, a period of nearly sixty years, this subject has claimed the attention of the medical world, and still many points call for discussion. How shall we find this invisible substance? The journal mentioned above contains four articles relating to the tests to be employed, showing that not yet have we reached a satisfactory agent or agents. What does its presence indicate? some fatal form of kidney disease in the pregnant woman, or a simple condition which shall disappear with the birth of the child? Does its presence always point to a morbid condition somewhere, or can it be found in the urine from a perfectly healthy body? Whence comes it, from the blood primarily or from that fluid altered by the cells of the tubuli? These and many more are questions still unanswered, and until they are, each and all of us may be pardoned for discussing a subject sixty years old at the least.

The first question which presses for an answer is how shall we discover the existence of albumen in a given specimen of urine? The agent or agents used must show the presence of albumen with absolute certainty, the reaction must take place quickly, the application must be easy and free from danger, and the materials must be in such a form as to be conveniently carried. The search for such a chemical or other agent which shall combine in itself all these conditions has occupied the thought of our best men, but thus far without effect; we know of nothing which will fulfil our desires in this matter. The most important element is that of certainty; and any agent or set of agents, no matter how they may fail in all other respects, if we can always depend upon them to point out the presence of albumen, are the ones to which we must resort, and such we find in heat and nitric acid; they possess this quality of certainty in a pre-eminent degree. The objections to them are, however, obvious, the acid being so unpleasant to handle, and its powerful destructive properties making it necessary to employ care in its use: the heat is not always available. I mean clean heat, like that from an alcohol lamp. In spite of these objections these agents, up to the present hour, are the final resort in all cases of doubt, if aught else is used. Roberts says the best tests for albumen "are coagulation by boiling and nitric acid," and again, "the clear superiority of nitric acid in regard to the precision of its indications is an inducement to seek for some means whereby its objectionable qualities may be mitigated." Da Costa remarks, "there are several other methods enabling us to ascertain the occurrence of albumen. Of these the chief are: heat, which coagulates the albumen; nitric acid, which causes a white precipitate. Of all the proposed substitutes for heat and nitric acid, probably none has come so near our ideal as picric acid, an agent comparatively clean, easily carried and readily applied, but experience with it shows it to lack certainty." As Dr. Harris well observes, "in the majority of cases its results are perfectly satisfactory, and it detects a very minute quantity of albumen; but I feel sure that occasionally it gives no indication of the presence of albumen when a small amount of it is undoubtedly present, as shown by other tests, and still more frequently does it give a reaction which is indistinguishable from that which a trace of albumen produces, but which is not due to albumen. * * * Specimens of urine containing mucin and no albumen, give a reaction with picric acid which cannot be distinguished from that produced when albumen is present." It will throw down mucin and peptones, leaving us in doubt, which must be cleared up by other agents.

Metaphosphoric acid is an extremely delicate test for albumen, but we find its solution

very unstable; as a solid, it deliquesces, dissolves but slowly, and any undissolved portions in the test-tube are removed with difficulty.

Yellow prussiate of potash with acetic (citric acid) offers attractions from the fact that it can be put into pellets and so be convenient for use and easily carried, but its deep staining qualities and difficulty of manipulation render it objectionable, and more than all, it will throw down mucin. Albumen tests of a valuable and attractive form are slips of paper, like slips of litmus for acid testing, and as such have been prepared with potassio-mercuric oxide. They were tried, but it was found that all urines are affected by the test more or less, so this has been abandoned. A most convenient test suggested by Dr. Roberts, because it can be made at any time and readily, is that of acidulated brines; but this will throw down the peptones, and the doctor gives it but slight mention in his last work. An approach to the abolition of the very objectionable features of nitric acid is the addition of five volumes of a solution of sulph. of magnesia to one volume of the strong acid. Dr. Roberts claims first that the mixture is colorless, will not fume nor burn, of such sp. gr. (1.240) that it will readily sink to the bottom of the test-tube, is more prompt and sensitive than the pure acid, and acts less strongly than the pure acid upon the coloring matter of the urine. Dr. Harris, in the *Medical Chronicle*, amply confirms these statements. It is to be used in all respects as the pure acid.

In view of all these facts, and we have only noted a few of the best agents suggested, we must still assign the heat and nitric acid the first place.

Having determined the presence of albumen, what does it signify? Does it mean that we have a something abnormal, or can it be present and the individual be in a thoroughly healthy condition? Observation and experiment seem to point to the fact that urine containing any considerable quantity of albumen is from an unhealthy body; the disorder may be slight, but good health is not compatible with well-marked albuminous urine.

(*To be continued*).

THE EARLY DIAGNOSIS OF PREGNANCY.*

BY E. S. M'KEE, M. D.,
Of Cincinnati, O.

The author considered the "opprobrium obstetrici" our inability to make a prompt and positive diagnosis of early pregnancy. Reliable evidence is sadly deficient in the first months. This fact in mind, he turned his attention to the symptoms of the first trimestrium, particularly those of late discovery. First were considered those signs which might occur at the time of conception. A number were mentioned, but the only one thought to be of any value was the peculiar voluptuous sensation and more general erethism experienced on fruitful intercourse. An enumeration of the symptoms of early pregnancy, generally known, was then made. What was true of the first of these, absence of menstruation, was true of them all, viz., there are numerous exceptions to any one of them, and the same condition might be produced by other causes; hence very unreliable testimony.

Among the later signs was mentioned that of Jacquemier, the slate or purple color of the vagina. Anything which impedes the circulation may cause this appearance. Dr. Joseph Tabor Johnson has made a good suggestion. He thinks the principles of the telephone could be used to hear, much earlier than usual, the feeble sounds of the fœtal circulation. Dr. S. C. Dumm thinks he can diagnose pregnancy as early as the fourth week, by the odor of the vernix caseosa upon the examining finger. Dr. E. C. Gehrung was able to make the diagnosis by the fifth or sixth week by the sensation imparted on touching the ovum with the sound. This is rightly condemned as a dangerous practice, while it may be simulated by a polypus or other foreign body in the uterine cavity, and in the early weeks the ovum is only attached to parts of the uterine walls, and the sound may glide by. Pinard and Didsbury have treated of a gingevitis which begins about the second month. Jerrisenne, basing his observations on the law formulated by Graves, that in hypertrophy of the heart the radial pulse remains the same whatever the position of the body, maintained that instead of the usual variation of from ten to twenty beats in the non-pregnant woman, the pulse of the impregnated remains the same. The essayist and others had investigated this symptom, and found it quite unreliable. Dr. H. B. Fry thinks that a rise in temperature in the cervix to one degree or more above the temperature of the axilla is a strong presumptive evidence of impregnation, provided there is no local disease. The author had found this true, but had found the rise of temperature in the vagina to be of loss value.

* Abstract of paper read before the Am. Med. Association.

To Hegar, of Freiburg, we are indebted for the new sign of great promise, which bears his name. This consists of an unusual resilience, compressibility, softness, bagginess, yielding, and thinning of the lower uterine segment; that is, the section immediately above the insertion of the ligamenta sacro-uterina. The shape assumed is that of a fan, balloon, or jug. The change is most apparent in the median line. According to Campsa, the examination should be made as follows: The thumb is introduced into the vagina until it reaches the cervix, and the index into the rectum until it reaches the ligamenta sacro-uterina; the other hand is placed over the abdomen immediately above the symphysis, and pressed down towards the finger in the rectum. The rectal finger explores the cervix and the lower uterine segment in all its parts, and lastly the higher parts of the uterus. The examination is facilitated by pulling down the uterus with the volsella and evacuating the bladder and rectum. The author thought this mode of examination thorough, yet repulsive to both patient and physician, as well as a difficult and hazardous procedure. He thought it quite possible in the majority of cases to make out all that is necessary with the finger in one of the culs-de-sac and the other hand externally. If this is not sufficient, it would be quite proper to make the examination as above described.

The bladder distended with urine and the uterus with menstrual blood may simulate Hegar's sign. These can be easily differentiated. Hyperplasia would show increased density. Subinvolution would increase the longitudinal as well as the transverse diameters. In marked retroversion a careful examination per rectum is often necessary to find the sign.

Dr. Reinl, formerly assistant to Hegar, says: "Among the 22 cases, I missed this sign but twice, and found it earliest in the fifth week of pregnancy." Dr. Campes, present assistant to Hegar, has reported six cases. Dr. E. H. Grandin, of New York, reports 18 cases, and says he can make the diagnosis prior to the eighth week by Hegar's sign alone. The author had a number of cases under observation, most of which had not yet had time to develop. One, a widow, acknowledged the opportunity, and believed herself pregnant. Repeated examination failed to find Hegar's sign, and she was assured that she was not pregnant. After 13 weeks the menses returned, and were normal in amount and duration. The other was a young wife, who, after a four months' absence from her husband, returned to him February 9th. She soon came under the author's care, and her case required a digital and specular examination two or three times per week. Three times in the sixth week Hegar's sign was made out. March 31st, 48 days after her return, she miscarried.

There remains to us, then, again to lament our inability, in many cases, to make a positive diagnosis of early pregnancy, to mourn the fallibility of many of the new and all of the old symptoms, and to especially recommend the sign of Hegar, which until now has proven itself impregnable, and to plead for investigators in a field which should not be "barren or unfruitful."

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Thursday, April 1, 1886. The President B. F. Baer, M. D., in the chair.

Dr. E. P. Bernardy read a paper on

The Value of Biniodide of Mercury as an Antiseptic in Obstetrics.

(Discussion on Dr. Bernardy's paper.)

Dr. Chas. Hermon Thomas had heard the statements of Dr. Bernardy with interest, and surprise that cases of so much gravity could be controlled by such simple means as vaginal injections. His practice and belief has been that such cases require the introduction of washes into the uterus, the washing of the vagina being utterly futile. The doctor related an instance in which a quartipara was allowed to die of septicæmia, no effort being made to wash out the uterus, although vaginal antiseptic injections were frequently employed in the case. Six weeks have elapsed since the death of that patient, and in that time the same practitioner has lost three additional parturient patients.

Dr. Longaker spoke in support of Dr. Bernardy's practice. We have been led to expect a prompt fall of temperature from the use of intra-uterine injections in septicæmia post-partum. His own plan is to discontinue intra-uterine injections after the first thorough washing, unless offensive discharges come from the uterus. He has observed that after the repeated introduction of forceps into the uterus the introduction of the hand or other means favoring the introduction of air, a peculiar traumatic metritis

results; and to relieve this he has been in the habit of introducing into the uterus an iodoform pencil, containing about 1⅔ drachms of iodoform; this prevents future sepsis. (See Lusk, last edition.) Prompt lowering of temperature and pulse are the result if this is used after sepsis has occurred, and even when antiseptic uterine injections have failed. The effect of one of these pencils will last through two or three days, when another may be needed.

Dr. Howard A. Kelly drew attention to the fact that the biniodide of mercury is almost, if not entirely, insoluble in water, and that an alcoholic solution would scarcely be admissible. He also called attention to the frequent presence of the bichloride as an impurity. He read the following letter from Dr. Francis L. Haynes:

"In reference to the potassio-mercuric-iodide, I may add a little to the facts I mentioned in our conversation. The last case of puerperal septicæmia I have seen in my own practice, occurred in Mrs. F., confined December 18, 1885. It was due to the fact that my hands were contaminated with septic matter, and that I trusted entirely to hard scrubbing and inunction with oil of turpentine to purify them (after Goodell). In this case the pulse was 138 and temperature ran up to 105°, but she recovered in a few days under copious injections of hot water into the uterus (generally plain, but sometimes with a little carbolic acid added). Three injections were given, and during the days on which this treatment was being used I attended several cases of labor, purifying myself with 10 per cent. solutions of carbolic acid. These cases had no trouble; but I became ill, as I always do when I use much carbolic acid, and my hands became sore. I now began to use the potassio-mercuric iodide solution to purify my hands, and since then have had no trouble whatever, although I have attended cases of labor within a few hours after (1) washing out the uterus of a patient of Dr. L.'s suffering from septicæmia (terminating fatally); (2) after amputating finger and metacarpal bone of a man suffering from gangrene of finger and suppurative cellulitis of the hand and wrist; (3) after digging out putrid placenta after miscarriage (several instances); (4) after performing autopsy in a case of suppurative peritonitis and bathing my hands freely in the pus. The solution may be used without apparent injury to purify blunt instruments, and it is certainly a great comfort to soak your speculum thoroughly in it after treating a case of gonorrhœa.

How is this solution prepared? A four-ounce bottle is marked with a diamond so as to indicate drachms, and filled with distilled water containing ʒj each of potassium iodide and mercuric iodide. (The cost of this solution is less than ten cents.) It is now a very easy matter to make a solution of any desired strength extemporaneously. A tablespoonful to the pint—one part to one thousand—is the strength I generally employ; but after autopsies, I use one to five hundred.

How do I prevent my hands from becoming eczematous when using this solution? Once or twice daily, after washing the hands and while they are still damp, about fʒss of glycerine is poured into the palm and thoroughly rubbed into the whole surface of the hands, which are then dried as usual. This is very effectual.

Dr. Wm. Goodell has had no experience with biniodide of mercury, but has had with bichloride. He is not sure that Dr. Bernardy is at fault in confining his antiseptic injections principally to the vagina, for where does sepsis usually take place? Not in the uterus, but through wounds of the vagina. In the Charlotte Hospital they have good results from the use of bichloride injections and iodoform. When the Preston retreat was new they had a good record; but afterwards the percentage of fatal cases became too large. This fault was remedied by the use of bichloride of mercury as a vaginal injection and the introduction of ʒj of iodoform. The pads to catch the lochial discharge were replaced by absorbent cotton, medicated with corrosive sublimate. In the last one hundred and forty cases no rise in temperature has occurred during the puerperal period. In these cases the antiseptic applications were all directed to the lower portion of the womb and the vagina. Dr. Bernardy is probably right. A solution of 1 to 2000 is too strong, and will produce soreness after operations. He does not like to have the patient on her side during and after the removal of the after-birth, as it favors the entrance of air into the vagina, as in Sims' position. She should be on her back.

Dr. Harris inquired if Dr. Bernardy did not use uterine injections after the removal of the dead fœtus. The effect of a decomposing fœtus with unbroken membranes within the uterus has a remarkably prostrating effect upon both mind and body of the mother.

Dr. Githens described a case of post-partum septicæmia in which an offensive leucor-

rhœa which had existed before labor, and which had been neglected, was the apparent cause. In this case vaginal injections of potassio-mercuric-iodide quickly relieved the undesirable symptoms.

Dr. Thomas thought vaginal injections would be quite sufficient as a prophylactic agent: but would it be considered sufficient if septic peritonitis were present? One thorough uterine wash first and then iodoform pencils to prepare for subsequent vaginal washes. In Bellevue Hospital uterine injections are always used when vaginal washes fail to reduce the temperature.

Dr. Bernardy uses the first injection himself and thoroughly washes out the uterus, and continues the injections until the fluid comes away perfectly clear. The firm contraction of the uterus eliminates the liability of absorption there, and the principal abrasions and absorbing surfaces are undoubtedly vaginal. The results at least have been satisfactory.

The pellets exhibited are quite soluble, and are chemically pure; the biniodide has been tested for bichloride, and none is present. The potassium iodide present merely aids in the solubility, without affecting the chemical composition of the mercuric iodide.

Dr. Wm. Goodell read a paper by Dr. Hiram Corson on the statistics of 3036 cases of labor.

NEW YORK NEUROLOGICAL SOCIETY.

Dr. C. L. Dana reported a case,

Total Trigeminal Paralysis, with Alternate Hemiplegia,

and discussed the question of the

NERVE OF TASTE.

The patient was a single man, aged 35, under treatment by Dr. George L. Fox for eczema of the scalp. He had always been healthy, and gave no history of syphilis or excessive indulgence of any kind, except in athletic sports.

In August, 1885, he was attacked with a trigeminal paralysis on the left side, affecting all of the sensory branches of the fifth cranial nerve, and to some extent probably the motor branch. The paralysis came on without any other complicating symptoms.

In December, 1885, he was attacked with a crossed hemiplegia, affecting the right arm and leg and the right side of the face. When seen by Dr. Dana in consultation, the paralysis was found to be not very complete, that of the face especially not being very marked. There were no sensory, and only very temporary speech disturbances.

There was complete anæsthesia in the distribution of the left trigeminus, but no loss of taste on either side of the tongue. The patient soon recovered in a considerable measure from his crossed hemiplegia, but the sensory paralysis remained unchanged.

In January, 1886, the patient had an attack of left hemiplegia.

Dr. Dana discussed the question of the nerve of taste, and referred to the contradictory opinions at present held regarding it.

Most authorities now believed that the glosso-pharyngeal supplied taste to the posterior third of the tongue, and that the fifth nerve supplied the anterior two-thirds, sending fibres to it via Meckel's ganglion, the great superior petrosal, seventh nerve, and the chorda tympani. Gowers had recently declared that the sense of taste was supplied by the fifth alone.

The speaker presented a review of all the evidence so far collected, and came to the conclusion that the glosso-pharyngeal was probably the sole nerve of taste. In his own case the lesion was probably a small hemorrhage in the lower part of the pons.

DISCUSSION ON DR. DANA'S PAPER.

Dr. Samuel Sexton said that ten years ago it was considered proper to divide the chorda tympani for tinnitus aurium, and it was supposed to have been done. This nerve has a long and circuitous course through the tympanic cavity, and is surrounded by a sheath of mucous membrane liable to inflammation in the acute purulent processes of the ear, especially in children. He had seen and studied a large number of cases in which, owing to acute purulent inflammations, there was complete destruction of tympanic contents, including the chorda tympani. There was no alteration of the sense of taste, though the tests to discover such an alteration were carefully made.

An Italian writer has called attention to the chorda tympani as a nerve in intimate connection with speech: that certain word sounds could not be found when it was absent. But Dr. Sexton's experience had not verified this. Taste was a complex function, which was developed slowly by cultivation. When tympanic membrane was absent, so that a probe could touch the inner wall of the tympanum, a variety of reflexes could be evoked, such as vomiting, coughing, sneezing; secretions, especially in the region of

the tonsils and pharynx, were increased, as also the saliva.

Dr. M. A. Starr reported ten cases of total anæsthesia following neuralgia of the trigeminus, in which there is no loss of taste. In his study of the lesions of the medulla and pons, there was no record of loss of taste, though all the cranial nerves, except the ninth and tenth, were involved — all of which would support the views advanced by the author of the paper.

Dr. A. D. Rockwell had seen many cases, and instanced one in which there was neuralgia of the seventh and fifth pair of nerves, accompanied with loss of taste.

Dr. Dana, in closing the discussion, thought the cases cited by Dr. Sexton showed that the chorda tympani does not carry the nerve fibres of taste at all; that they were proof that they must take another course from that described by most of the text-books. It hardly seemed probable that they had so complicated an arrangement as that claimed by Gower, which he showed by means of a diagram.

Vaso-motor Neuroses.

Dr. M. Allen Starr, the author of the paper, said that under this title it was intended to include a series of disturbances of circulation and nutrition whose causation could be traced to disorders of the nervous system. He selected this subject because it was one which had been somewhat neglected in the discussions of this society, and because no definite summary of the present state of knowledge of the physiology of the vaso-motor action had lately been presented, and because he had recently seen a number of cases which might be classed together under this title, and which he wished to have discussed by the members present.

Disturbances of the circulation might occur in any part of the body, and were to be regarded not as distinct diseases of the parts in which they occurred, but as symptoms of lesions of the peripheral or sympathetic or central nervous system. At the present time, however, it was impossible to make a pathological classification of these symptoms, and therefore they might be discussed together. In treating of the subject of vaso-motor neuroses, the discussion of the physiology and pathology of the vaso-motor system could be united with advantage.

Since changes in the force and frequency of the heart's action and variations in the total amount of blood in the body affect the body as a whole, the state of the circulation in any one organ or part depends largely upon the degree of contraction or dilatation of its vessels. This is known as the local vascular tone. It is under the control of the system of nerve ganglia with their subservient fibres, which are found in the smaller arteries. The energy expended by these ganglia is manifested by a constant contraction of the circular muscular coat of the artery, a contraction which is constantly opposed by the dilating force exercised by the blood pressure within the vessel. In a state of health an exact equipoise between these forces never occurs. Variations, however, in the vascular tone are produced either by local influence or by influences reaching the ganglia from a distance, through the vaso-constrictor or vaso-dilator fibres. The constant manifestation of energy in the maintenance of arterial tone does not have its only source in the local ganglia, but is derived partly from the central nervous system through the vaso-constrictor nerves. Here the experiments of Claude Bernard were detailed. From these experiments it was concluded that a dilatation of the vessels follows—

1. A paralysis of the local ganglia in their walls.
2. Separation of these from the sympathetic ganglia.
3. A destruction of the sympathetic ganglia.
4. A separation of these from the spinal cord by division of the anterior spinal nerve roots.
5. A disintegration of the cord.
6. A separation of these centres from the medulla.
7. The destruction of the medulla oblongata.

The action so far considered has been wholly of a vaso-constrictor kind, and the dilatation mentioned has been due to a suspension of constrictor energy, normally passing outward. This is a passive dilatation. But further experiments have shown that another kind of dilatation may be produced, due to an impulse of an active kind sent to the local ganglia by the vaso-dilators. This is an inhibitory impulse arresting the constrictor action of the ganglia in the vessel walls in spite of the continued energy sent them from the central nervous system by the constrictors. Here the experiments on vaso-motor dilatation were given, and the various theories of the mechanism of dilatation in the vessel walls; it being concluded that there was no mechanism in the wall which could produce a dilatation, and that a dilatation was due wholly to the blood pressure within overcoming constrictor action.

The subject of vaso-motor reflexes was then taken up, and it was shown that the seat of these reflexes was in the dorsal region of the spinal cord, since all vaso-constrictors and vaso-dilators can be traced to that region. The particular area of the spinal cord covering these reflexes was thought to be the gray matter surrounding the central canal and including the fascicular columns of Clarke. As bearing on this point, the author referred to the observations by Jacubovitch, Schultze, and Fürstner. It was impossible to say from these cases whether vaso-motor functions are located in the column of Clarke or in the gray matter around the central canal, or in both.

Vascular tone of the thoracic and abdominal organs is regulated by centres in the pons and medulla. Experiments of Bernard were related, and cases of diabetes mellitus and diabetes insipidus produced by lesion of the medulla and pons were mentioned. The influence of the vaso-motors in the production of functional disorders of the stomach and intestines was alluded to.

From this review of physiological experiments and pathological facts it becomes evident that the disturbances of vascular tone which are included under the title vaso-motor neuroses may be produced by many different causes acting upon many different organs. The author here mentioned a number of possible causes and their location, after which he gave the histories of seven cases of vaso-motor neuroses, with remarks on the same. These cases seemed to illustrate some of the conditions which have still to be classed under the term vaso-motor neuroses, from want of a more perfect knowledge of their nature. They appear to be little noticed in the books, and rarely discussed in societies; but they certainly merit careful study, inasmuch as they require cautious and scientific treatment.

DISCUSSION ON DR. STARR'S PAPER.

Dr. Sachs thought that some statements made by Dr. Starr elucidated some obscure points in experiments which he made several years ago on animals to discover the relation of the spinal cord to the secretion of the kidneys. Eckhardt had stated that section of the cervical spinal cord had the same effect as section of the medulla: that is, to inhibit the secretion. These experiments were difficult, because of the necessity of keeping up artificial respiration, but they showed that urine was secreted as in health, though somewhat diminished in quantity. That it was actually secreted was proved by introducing chemical substances into the blood, the coloring matter of which was shown in the urine secreted. The results obtained by Eckhardt were probably due to peripheral irritation caused by laying bare the ureters, which interfered with the secretion of the kidneys. He asked Dr. Starr what views he advanced with reference to the course of the vaso-constrictor nerves.

Dr. Starr replied that one theory was that they passed from the lateral tracts of the cord through the fourth, fifth, and sixth cervical, and into the sympathetic system, and thence to the viscera. Another was that they entered the sympathetic as far down as the level of the first dorsal. There was an intimate connection with the kidney. Experiments high up in the cord would, of course, produce diabetes.

Dr. Sachs said that in his experiments high up in the cord there was no diabetes.

Dr. C. L. Dana considered himself indebted to Dr. Starr for so able a paper. The local vaso-motor ganglia had been assumed to exist, but had never been satisfactorily demonstrated as physiological entities. Vaso-motor disturbances were common as symptoms, and were so considered, rather than as a distinct disease. Accompanying them there were almost always marked sensory and trophic symptoms, especially if chronic, and they had made an effect on the system. In this class of cases were those vaso-motor troubles of the extremities, and such as digiti mortui, and mild types of renal disease; an independent disorder, flushing of the ears, Basedow's disease and diabetes, which should also be ranked among these. It gave rise to confusion to consider the vaso-motor system as independent, in the same way as the sympathetic system, forgetful of the relation of both of these to the cerebro-spinal.

Dr. Weber spoke of the connection of sciatica with diabetes. While sugar was found in the urine of patients suffering from protracted sciatica, there were few cases of well developed diabetes in which there was sciatica. He related three cases of sciatica in which there had been sugar in the urine, and the attending symptoms of diabetes. He had seen cases where sugar was present *after* sciatica; but he was doubtful if cases of true diabetes were developed by sciatica.

Dr. Leszynsky related two interesting cases of vaso-motor disturbances. He questioned if cold was not a factor to be considered, since a case of symmetrical gangrene under his observation would have relapses on cold days. Chilblains were common in winter.

Dr. Starr, in closing the discussion, re-

marked that the vaso-motor local ganglia had been very recently demonstrated by French physiologists in frogs, rabbits, and cats. He did not intend to give the impression that sciatica caused glycosuria, but referred to those cases, quite a number of which were on record, where there was a sudden appearance of sugar in the urine, which afterward disappeared.

CLINICAL SOCIETY OF MARYLAND.

Stated meeting held March 19, 1886.

Paralysis of the Arm Following Injury.

Dr. W. B. Platt presented a patient suffering from paralysis of the muscles of the left arm. The man has a history of a fall from an elevation of twelve feet, striking upon the left anterior side of the head and remaining insensible for ten minutes, after which he regained consciousness and walked without assistance to his home, a distance of about one mile. The paralysis is at present confined to the abductors of the arm; the muscles of the forearm, beyond a little stiffening from want of use, are not affected.

On the surface of the man's body is a copper-colored eruption, strongly suggesting a syphilitic infection, although the patient firmly denies ever having had a chancre. Behind one of his ears is an enlarged gland.

His paralyzed muscles give almost no response to the strongest faradic current.

There has been neither pain nor swelling at the shoulder at any time. The paralyzed muscles are slightly atrophied, as may be seen by comparing them with those of the opposite side.

On the left side of the head, anteriorly, there is a depressed cicatrix.

Dr. Platt exhibits this case for the purpose of getting the opinion of the members present whether the paralysis is of a syphilitic origin, or whether it is due to an injury to one of the convolutions of the brain underlying the point of injury to the head.

Dr. E. G. Waters: What is the patient's occupation? Has he ever been exposed to the poisonous influence of lead?

Dr. Platt: By occupation the man is a carpenter. He has not, to the best of my knowledge, been exposed to the toxic action of lead.

Dr. Waters thinks the paralysis due rather to a blow on the shoulder than to the fall on head. If resulting from the head injury, it would be on the opposite side.

He had treated a man who fell from the top of a car, striking on his shoulder, and resulting in complete paralysis of the right deltoid muscle. Three weeks from the time of injury, the man's general condition being good, a blister was applied over the paralyzed muscle. After the epidermis was removed the surface was sprinkled with a small amount of powdered strychnia. After four or five weeks of this treatment the muscle regained its normal tone, and recovery was complete.

Dr. John Chambers: Did Dr. Platt's patient ever complain of a pain in the shoulder?

Dr. Platt: He never complained either of pain or swelling at the shoulder.

Dr. Joseph T. Smith: Has any improvement been observed as a result of treatment?

Dr. Platt thinks he has noticed a very slight improvement in the muscles since the faradic current has been used.

For a few days the man was on the iodide of potassium, but lately has been taking the biniodide of mercury.

His individual opinion regarding the condition is, that the man has sustained an injury to one of the cerebral convolutions, and being constitutionally tainted by syphilis, the injury has, in consequence, become chronic and given rise to this paralysis; whereas, such an injury to a convolution of the brain in a healthy individual would have passed away without giving rise to any permanent trouble. As to the paralysis occurring on the same side as the head injury, he thinks this may be accounted for by non-decussation of the fibres coming from this convolution. Such anomalies are known to occur.

Dr. J. H. Branham don't believe that non-decussation occurs with sufficient frequency to justify us in using it as a factor in diagnosis.

Dr. Platt only suggested its possibility, he did not offer it as his opinion.

Dr. John Chambers thinks the paralysis peripheral, and due to a neuritis. The difficulty would be extreme in locating the centre that might be involved in causing such a paralysis.

Dr. G. H. Rohé: Does Dr. Platt exhibit this eruption as a syphilitic one?

Dr. Platt takes it to be syphilitic, although the man firmly denies any primary infection.

Dr. Rohé thinks the brain lesion has appeared rather too early to be syphilitic. It is remarkable that brain and skin lesion should appear at the same time.

Dr. Platt, in closing the discussion, said, as to neuritis, he had failed to get any history or find any local evidence of injury that would suffice to cause a neuritis. As to the

early appearance of cerebral lesions in syphilis, much has been done on the subject in Germany, and it is found that they occur with much greater frequency than was at first supposed.

Dr. W. J. Jones next read a paper on a case of

Encapsulated Pelvic Peritonitis.

Dr. W. Pawson Chunn: Was the woman examined in knee-chest or in Sims' position, with Sims' speculum, to see if any opening or fluctuation could be found?

Dr. Jones: She was, but neither any opening nor fluctuation was present. Some slight induration was felt on left side.

Dr. N. G. Keirle asked if the ulcer found in the ileum might not have occurred primarily, and caused a slight perforation, with a secondary peritonitis.

Dr. W. T. Councilman said the ulcers in the ileum were of too recent origin to have been, under the circumstances, anything but secondary. Without doubt they were secondary to the tubercular peritonitis. It is his opinion that the infection took place previously in the lungs, spreading thence to the pleura and peritoneum, and finally to the intestinal tract.

Dr. William Pawson Chunn exhibited specimen and related a successful case of

Ovariotomy with Supra-vaginal Amputation of the Uterus in a Negress.*

DISCUSSION.

Dr. J. Edwin Michael: Had Dr. Chunn added *endurance* to his remarks concerning the woman's courage in refusing to take an anæsthetic, it would not have been amiss. He had had the pleasure to witness the operation reported by Dr. Chunn, and congratulated him on the success of the case. He was compelled, however, to differ with Dr. Chunn in regard to the necessity of performing hysterectomy. An examination of the specimen will show that the uterus is free from adhesions to the tumor on both its anterior and posterior surfaces, and is only connected with it by means of adhesions to the broad ligament. The tumor, in other words, having its proper pedicle on one side, had become adherent to the broad ligament on the other side, and these adhesions could have been ligated and cut, and the tumor removed, as is usual in such cases, with less danger to the life of the patient than that to which she was exposed in the operation done.

Dr. W. B. Platt thought the true character of clean urine, like the fluid referred to by Dr. Chunn, could have been positively made out had it been subjected to chemical and microscopical examination.

Dr. W. E. Moseley: By examination of the specimen presented, any one would, without hesitation, agree with Dr. Michael, that tumor could have been removed without taking out the uterus.

Dr. Chunn, in closing the discussion, said that in spite of such formidable opposition, he still held his original opinion that it was impossible to remove the tumor and not the uterus. Dr. Michael probably differed with him because the relations between this tumor and the sac were very different after removal from what they were *in situ*. This was simply because the sac and uterus were amputated obliquely, and hence the specimen as shown does not exhibit the full and true relations of the parts.

He did not remove the other ovary because he could not find it. He referred to a case in which such an omission had been made, and in which, in consequence, there was an extra-uterine pregnancy through the remnant of the cervical canal.

Gunshot Wound, Diverticula of Trachea and Œsophagus.

Dr. W. T. Councilman exhibited specimens from a very interesting case of gunshot wound. Also, two specimens of diverticula, the one a diverticulum of the œsophagus, the other a diverticulum of the trachea. The one in the œsophagus was near the pharynx. It was of the ordinary pressure variety—that is, there is a want of development of the muscular tissue at the point, and in consequence, pressure brought to bear causes a sacculation of the mucous membrane. There was a grain of corn in this sac. The one in the trachea occurred on its anterior surface a little way above the bifurcation. It is difficult to classify it as a traction diverticulum, because there was no evidence of any adhesions ever having been contracted.

Dr. E. G. Waters thinks Dr. Councilman's theory respecting the force of the explosion having taken place beneath the skin, a correct one. He takes it, it was the result of the delayed explosion of an excess of powder used in loading the pistol. Persons unaccustomed to the use of firearms make a common mistake of employing too great a charge of powder, and in consequence the excess is not exploded until after it leaves the weapon, or, if not projected against a resisting substance, may not be ignited at all.

Dr. Waters has proved this, to his mind, by experiments he has made by firing charges of powder over white surfaces, such as snow or sheets spread upon the ground.

*Maryland Medical Journal of March 28, 1886.

Dr. John Hemmeter thought the rupture of the liver might have resulted from the sudden admission of air into the thorax.

Dr. F. R. Nordman related a

Case of Trichinosis,

and showed microscopic and macroscopic specimens. The condition was not diagnosed ante-mortem.

Dr. N. G. Keirle thinks trichinosis may be acute or chronic. He has observed a dysenteric condition of the bowels co-existent with trichinosis. Thinks this dysentery of trichinous origin.

The case reported by Dr. Nordman he takes to be a chronic one, and in his opinion the evidence of a former dysentery, as was seen in this case, was one of the acute lesions.

The first case that he saw was the one recently reported as occurring at the City Hospital—the clinical diagnosis was suggested by Dr. Bressler, and was then worked up by Prof. Bevan.

Dr. G. H. Rohé thinks many of the old rebellious dysenteries may be of trichinous origin.

Dr. L. McLane Tiffany don't think old dysentery a recognized symptom of trichinosis.

Abnormalities of the Aorta.

Dr. Randolph Winslow exhibited a rare specimen of anomalous condition of the great trunks arising from the arch of the aorta, as well as of the aorta itself. The specimen was taken from the body of a negro man, which race seems to be particularly prone to anatomical variations. The aorta passed between the œsophagus and spinal column, and then passed down in the regular manner. There were four trunks given off from the arch, as follows: 1, left carotid; 2, right carotid; 3, right subclavian; 4, left subclavian. The left carotid passed obliquely in front of the trachea to reach the left side, thus enclosing this tube in an arterial ring, which would be in danger of injury during tracheotomy.

Dr. Winslow said the aorta was liable to a variation in the number of the trunks arising from the arch, which sometimes consisted in an increase, sometimes in a diminution. The present specimen was one in which there was both an increase and transposition of these branches. The increase to four trunks might be produced by simple fissure of the innominate, or by an abnormal left vertebral, or by an abnormal right thyroid, or thyroidea ima. Probably the most frequent increase was the origin of the left vertebral from the arch. When the innominate was absent it was frequently noted that the right subclavian arose from the extreme left arch below the left subclavian, and then passed behind the œsophagus to reach the right side. The number of trunks arising from the arch might be diminished in various ways, the most frequent being the origin of the left carotid from the innominate, as in a specimen which was exhibited by the doctor.

Dr. H. Clinton McSherry presented a specimen of

Pyridin.

It was first described by Anderson in 1851. It is obtained from oils which are the result of distillation of bones. He has used it successfully in a case of asthma occurring in a very neurotic woman. The method of administering it is by the inhalation of its vapors. About ʒij may be poured into a saucer and allowed to stand uncovered for about one hour and a half in a closed room in which the patient is confined. This may be repeated three times a day. The relief is, as a rule, marked.

Editorial Department.

Periscope.

The Tuning-fork in Diagnosis of Lesions of the Internal Ear.

Dr. P. McBride thus writes in the *Brit. Med. Jour.*, April 10:

Until quite recently it was, and by many aural surgeons it even now is, an accepted theory that, if the tuning-fork beheard byboneconduction better in the deaf or deafer ear, the labyrinth is intact. To those who have followed the otological literature of the last few years, it must be known that this rule is by no means without exceptions. Twelve years ago, or more, Cassells, of Glasgow, published a case in which, after exfoliation of the left cochlea, the hearing power actually improved, and all the notes of the piano were perceived. More lately, Schwartze and Christenneck had under their care a patient who, in spite of the loss of the right

cochlea, continued to hear the tuning-fork (C) by bone conduction louder in the affected ear. Jacobson, too, has recorded a case in which, notwithstanding suppurative disorganization of the cochlea, hearing by bone conduction was retained until just before death. The last contribution towards this subject is by Gruber, who records an instance of exfoliation of the two upper convolutions of the cochlea, associated with only partial loss of hearing on the affected side and retained bone conduction, Schwartze, in his recently published work. accepts frankly the position which alone is tenable—assuming, as we have every reason and right to assume, that these observations are accurate. According to the author, retained bone conduction only proves the trunk of the auditory nerve and its centre to be sound, but does not necessarily imply a healthy condition of the labyrinth. But, even with this evidence before them, there may probably be found those who, on the ground that such facts are contrary to physiological common sense, will refuse them the consideration they deserve in clinical investigation.

The following is a brief record of a case which recently came under my observation: Mr. ——— some months since fell from a height, striking the right tempero-parietal region. He was stunned, and for two days could not stand. During this time, there was paresis of the right arm and leg. Giddiness was at first intense, and is still troublesome. His right ear has been deaf ever since. The tuning-fork (the large fork used by Politzer, furnished with brass clamps, and vibrating 512 per second), placed on the middle line of the forehead, was better heard in the right ear, and was also distinctly perceived from the mastoid of the same side. The same remarks also apply to a small fork of higher pitch. The giddiness is increased by turning from right to left, but not from left to right. The right ear is quite deaf, and even words spoken loudly through a conversation-tube are not heard. The drum-membrane on the right side was slightly depressed, but moved freely outwards on Valsalva's experiment—needless to say, without improving the hearing power.

Taking all the facts of this case together, we cannot but arrive at the conclusion that the labyrinth of the affected side was injured, either by concussion or fracture; and yet the hearing by bone conduction was not only as good as, but even better than that of the healthy ear. It did at first occur to me that a rupture in the continuity of the chain of ossicles might account for the symptoms, but the persistent giddiness could not be explained on this hypothesis.

This case, then, taken together with the evidence before adduced, proves to my mind that better hearing by bone-conduction is by no means certain proof of a healthy condition of the internal ear. It is well known and admitted that the converse proposition is also subject to numerous exceptions. Thus we meet with cases of chronic middle-ear catarrh, in which bone-conduction is interfered with, and which are readily amenable to treatment. In acute inflammation of the tympanic cavity, the same state of matters is often produced.

To discuss this matter in all its bearings would occupy too much space, and would, I feel, in the present state of our knowledge, be of but slight value. I cannot help, however, before I conclude, calling the attention of those who are interested in otology to the fact that the time-honored tuning-fork test must now be considered as uncertain, whether in the positive or negative sense. No doubt it is a valuable aid to diagnosis, so far as we at present know, in a majority of cases; but then arises the question whether the number of exceptions may not increase more than we expect, as our knowledge augments.

Delusions, the Result of Intestinal Accumulations.

Dr. A. E. Bridger thus writes in the *Brit. Med. Jour.*, April 10:

I propose to bring under notice the following case of mental delusion, dependent on intestinal accumulation, and its resulting reflex derangement.

My patient, a lady, about 50 years of age, was brought to me with the following history: She had been married for twenty-nine years, and had brought up a family of six children, all of whom were healthy; no miscarriages. Her general health had been remarkably good all through her married life; she had been a good wife and an exemplary mother. She had passed the change of life without any marked nerve-derangement. Her family history was good; no traces were discoverable in it of mental derangement or of serious hereditary disease.

About a year ago, she began to lose appetite and flesh; her skin became harsh, dry, and yellowish in tinge; her digestive powers became greatly impaired; once or twice there had been some vomiting of blood, and a troublesome dry cough had developed itself. These symptoms led, on the part of her family, to a fear of consumption, which fear was dispelled by a medical examination. Remedies, however failed to relieve her symptoms; and, about eight months ago, mental delusions began to show themselves. These at first took place invariably at night, and were, from first to last, of one class only—namely, that connected with taste and smell.

At first two or three times a week, and of late nightly, the patient would complain that some one was burning sulphur or phosphorus in the room. She would get up frequently to search the room for a man who, she supposed, was smoking. She became impressed with the idea that her husband and children produced these smells, in order to annoy her, and if possible to kill her; and twice she had left the house, and remained away for days, in order to rid herself of her supposed persecutors. The smells, however, followed her wherever she went, and she came to believe herself the victim of a wide-spread conspiracy. About this time she began to refuse food, alleging that it contained poison, and that she could distinctly taste arsenic and sulphur in everything that was prepared for her. She accused the grocer, the milkman, the baker, and the butcher, of attempts to poison her, and communicated her suspicions to the police.

When brought to me, her condition was as follows: She was much emaciated, and disinclined to talk, had a stupid and spiritless aspect, a cachectic look of the skin, yellowish conjunctivæ, etc. She made no special complaint, other than of the conduct of her friends. The bowels were said to be regular. The urine was thick, depositing lithates in abundance; no albumen or sugar. Examination of the special senses and of the chest resulted negatively. Inquiries about the abdomen elicited the fact that a sense of weight and of movement had latterly been much complained of, and I determined on making an examination of the part. On inspection, a curious state of matters became apparent. The position of the transverse and descending colon was occupied by a large elevated ridge, and the movements of the smaller intestine were distinctly visible through the thin abdominal walls.

It is scarcely necessary to add that the elevated ridge was produced by an immense collection of hardened fæces, which it took several days, with the aid of spoon-handles, injections of glycerine, castor oil, hot water, and the free use of mild aperients, to remove. The first scybalum passed was so large and hard that it actually once seriously occurred to me to place the patient under chloroform, and extract it with Simpson's short forceps.

It is now six weeks since the accumulations were removed, and in that time the patient has increased wonderfully in weight. She eats well and sleeps well, and most satisfactory of all, not a trace of her delusions remains. Her friends declare that she is in better mental and physical health than they have known her to be for the last ten years.

Corrosive Sublimate in Diphtheria.

Dr. Werner, medical officer to a circumscribed factory population of about 2,000 near Narwa, in the Gulf of Finland, writes in the *St. Petersburger Medicinische Wochenschrift*, describing the satisfactory results he has obtained in diphtheria by treatment with perchloride of mercury internally, combined with ichthyol inunctions. The disease is very frequent and fatal in the locality, he having attended during the last six years ninety cases, the average mortality of which was between 60 and 70 per cent., the majority succumbing from general weakness when the local affection was passing off, or after it had quite disappeared. Last year the type was peculiarly severe. In July, August, and September, eleven cases occurred, of which no less than nine proved fatal. From the end of September to the present time, however, during which period there have occurred seventeen cases, all of which were treated with perchloride of mercury, and many of which were very severe, there were only two fatal cases, neither of which was seen till a few hours before death. The author's method is as follows: For young children he dissolves a quarter of a grain of the perchloride in 4 oz. of water, for children of 6 or 7 half a grain in 6 oz. of water, and for adults three-quarters of a grain in 8 oz. of water. This solution is given to the patients while they are awake every twenty or thirty minutes, in measured doses, so arranged that the quantities made up shall last from twenty to twenty-four hours—*i. e.*, about half a drachm in the case of young children and a drachm in that of adults. When a good deal of sleep is obtained, larger doses are given at longer intervals. As a rule only milk is allowed as nourishment. If consid-

erable pyrexia exists, an enema of from ten to thirty grains of antipyrin, according to the age of the patient, is given, the rectum having been previously cleared out. Externally ichthyol is diligently rubbed in over the swollen glands three or four times a day, the fingers being wetted with water when dry to permit of the rubbing being continued for some time. For the first two days of this treatment the local affection usually undergoes no improvement, but on the third day it begins to diminish and the general condition becomes better, the appetite increasing, and the children regaining their wonted spirits. In no case did the author meet with the extreme debility which was frequent in cases treated by pilocarpine, even when the local affection was decreasing. As the patients approached convalescence the medicine was diminished, so that more than six bottles were never required. Complications never occurred, though three of the patients had previously had scarlatina.

Perforation of the Appendix Vermiformis During Pregnancy.

At a meeting of the Gynæcological Society of Dresden, Herr Korn gave the notes of a case of perforation of the appendix vermiformis. The patient was a hitherto healthy woman, æt. 35, who had been pregnant eight times from 1871 to 1884. In the beginning of this year she began to suffer from stabbing pains in the region of the stomach, and some days later from severe pains about the liver. The diagnosis was pleurisy and peri-hepatitis, and the patient was admitted into the lying-in institution in order to have labor brought on. She had last menstruated in the beginning of July, 1884. At the time of admission the temperature was 35·5° C., pulse 118. Marked meteorism and abdominal tenderness, making exploration of the outlines of organs impossible. Dulness from the symphysis to the navel. Os open, and ballottement easy. Diagnosis: peritonitis, pregnancy at six months. Treatment: ice-bags and opium. Coffee-ground vomiting followed the administration of opium. On the following day strong pains came on, and a rapid labor resulted in the birth of a premature child, which very soon died. The uterus could not be felt after the birth of the child, and the placenta could not be expressed. Ultimately the placenta was removed from the vagina by the hand. The uterus was atonic, filled with blood, and partially inverted. Injections of water heated to 40° C and of cold water were tried in vain to produce contraction. Strong vinegar injections were more effectual. Ergotin had also been injected hypodermically. Patient died on the fifth day.

Post-mortem examination revealed peritonitis produced by perforation of the appendix vermiformis. The appendix was adherent to the uterus, and greatly stretched longitudinally. The uterus, ovaries and cellular tissue were quite normal. The cæcum was stretched and lay immediately under the liver, to which it was adherent. The perforation of the appendix is held to have been traced to the softening resulting from an attack of typhlitis.

Pasteur on Hydrophobia.

The *Lancet*, March 6th, says: The total number of cases that have now been treated for the prevention of hydrophobia amounts to 350. The first 200 of the cases appear to have been submitted to the preventive inoculations more than two months ago. M. Pasteur asserts that statistics prove that in the majority of cases of hydrophobia in man the disease develops within sixty days of the receipt of the bite of a rabid animal. Consequently he claims that his treatment has been most successful, seeing that not a single case submitted to him, within a reasonable time after the bite, has developed any signs of hydrophobia. We confess that such a conclusion is in every way reasonable: it is reasonable, not so much from the statements as to time, as from the circu.mstance that so large a number is dealt withc It appears to be inconceivable that of 200 ases of certified bites from rabid dogs not one should be followed by hydrophobia, if the treatment be not assigned as the cause of the immunity. We could explain away the immunity if only a few cases were concerned, but hardly, we think, where so large a number of individuals have been bitten more than sixty days ago, and yet without any becoming the subject of hydrophobia. Only one case, which Pasteur unwillingly treated, has succumbed to the disease. This was the case of a girl who had been bitten thirty-seven days before he saw her. Symptoms of the disease appeared ten days later, and, if the case proves anything, it goes to support M. Pasteur's opinion, for the fatal result occurred well within the period above mentioned as the most probable time for the appearance of the disease. In science, and especially in medical science, caution at all points must be exercised; but if the success hitherto achieved by the Professor be maintained and strengthened by the further experience of a

few more months, the method will prove a boon to humanity, a gain to science, and justly merits the applause of the human race. M. Pasteur announced his intention last Tuesday of endeavoring to overcome diphtheria by measures similar to those adopted against small-pox and hydrophobia.

Traumatic Inguinal Aneurism; Rupture of of Sac; Ligature of Arteries.

Before the Clinical Society of London Mr. C. Mansell Moullin read a paper on a case of Traumatic Inguinal Aneurism; Rupture of Sac; Ligature of the Common Femoral and External Iliac Arteries. The patient, a man aged thirty-four, had received a severe blow in the groin from the edge of a flat piece of iron about four weeks before admission. There was a good deal of swelling and discoloration about the part for some days. Three weeks after receiving the blow the swelling reappeared, and continued to increase in size until the morning of admission, when, during an effort, he was seized with violent pain, and a large pulsating tumor made its appearance in the groin, extending into the scrotum and perineum. The foot and leg were not much swollen, but the skin in the groin was red and œdematous, and the scrotum much discolored. An incision was made into the swelling over the femoral artery (after an abdominal tourniquet had been applied), and a longitudinal slit found in the wall of the vessel, immediately under Poupart's ligament. A director was passed down it, the artery separated and tied below the injured part with catgut. A fresh incision was then made above Poupart's ligament, for the purpose of securing the external iliac above the rupture. No other vessel was tied. The blood-clot, some of which was old and very adherent, some quite recent, was turned out as far as possible, a large drainage-tube inserted, and the limb carefully wrapped up in cotton-wool. The subsequent course was perfectly simple, except that the wound suppurated freely, and, until a side opening was made, remained full of decomposing clots. The limb wasted exceedingly, and a small slough formed on the side of the heel, but the gangrenous patch was only the size of a shilling. Four months after, pulsation could just be detected in the posterior tibial, and perhaps in the anterior.

On the Use of Esmarch's Bandage in Local Anæsthesia.

M. Chandelux (*Lyon Médical*), advocates the application of Esmarch's bandage to a limb previous to the use of Richardson's ethereal spray, in those cases where his method of producing local anæsthesia is to be used. He points out that by this means the "freezing," or rather the anæsthesia, is accelerated and its effect prolonged. It is thus applied, *e. g.*, in the case of avulsion of the great toe-nail. The part has its blood driven out by the application of an india-rubber bandage from below upwards, commencing at the point of the toe, and a second bandage is then applied where this one ceases, say about the junction of the middle and lower thirds of the leg. The first bandage is then removed, the dorsum of the foot and four outer toes protected by padding, and the ethereal spray directed on to the great toe. Little or no pain is produced by thus Esmarching the limb. In cases where the part to be operated upon is much congested, as in the incision of a whitlow, this method is not advisable, as the anæsthesia is followed by a corresponding flow of blood, causing great pain.

The advantages claimed for this procedure are: 1. The anæsthesia is obtained in a period varying from 20 to 40 seconds, whereas by the ordinary method the average is about two minutes. 2. After cessation of the spray, when once the frozen area is produced, the anæsthesia remains for about three minutes, which is explained by the persistence in the arrest of the circulation, due to the Esmarch's bandage. All accession of heat by means of the blood stream is, in fact, entirely prevented. 3. There is, during the operation, no flow of blood to hide the parts to be removed. Hence, these may be carefully dissected, and we are certain of not leaving any portion either of the matrix or of the bed of the nail in the portion which it is proposed to destroy. There is said to be no risk of subsequent hemorrhage.

Anæsthesia of the Hand.

At a meeting of the Midland Medical Society, held on February 3, Dr. Suckling showed a man who had been under his care suffering from complete anæsthesia of the left hand (*The Lancet*, March 13, 1886). Ten months previously, in lifting an eighteen-gallon can of milk with a fellow-porter, his assistant dropped the can, and the patient suffered a severe strain of the arm; anæsthesia and paresis of the hand immediately followed. There was no trophic or electrical change, and the only symptom that might have indicated actual injury to the roots of the brachial plexus was a slight dilatation of

the left pupil, which might have been due to irritation of the root of the first dorsal nerve. Dr. Suckling concluded that the case was one of functional hyperæsthesia, and probably due to hypochondriasis, the man seeming depressed. The functional nature of the affection was proved by his rapid recovery after faradization, and by the fact that if, when blindfolded, a mark was made some distance below the line where he said he could feel, when the bandage was taken off he always felt down to this mark, so that a daily diminution of the area of anæsthesia was produced by deceiving him in this manner.

Reviews and Book Notices.

BOOK NOTICES.

The Principles and Practice of Surgery. By Frank Hastings Hamilton, M. D., LL. D., etc. Third edition, illustrated. 8vo. Pp. 989. New York: Wm. Wood & Co., 1886.

More than a dozen years have passed since the second edition of this work appeared, and during that time the science of surgery has made gigantic strides. To appreciate these the text has been subjected to a thorough revision, much of it being completely re-written, and large additions inserted.

The object of the author, as announced in the preface and consistently carried out in his pages, is to discard all historical and theoretical discussions, and to confine himself to the description of those methods which the long experience of the writer has proved to himself to be the most satisfactory. Hence the tone of the volume is throughout eminently practical, and by such limitation the possibility has been reached of presenting the whole domain of surgery within the compass of one volume not extravagant in magnitude.

The work is well printed, and the text is illustrated with 472 engravings on wood. The typographical arrangement is neat and well adapted for facility of reference. An excellent index closes the volume.

A Manual of Midwifery. By Alfred Lewis Galabin, M. A., etc. Illustrated with 227 wood engravings. 8vo., pp. 758. Philadelphia, P. Blakiston, Son & Co., 1886.

The accessory details which fill so many books on midwifery and increase them to a bulk which, like Falstaff's waist, is out of all reasonable compass for a manual, are omitted by the author of the present work, while at the same time he aims to include all that is likely to be required by students or practitioners.

Thus, he drops as of no importance in a treatise of the kind, the general anatomy of the female sexual organs, and many discussions on historical and theoretical points in the science. On the other hand, he claims for a number of views and directions in his pages the merit of originality, as they are the products and results of his own studies during the period that he has been obstetric physician and lecturer on midwifery at Guy's Hospital.

The arrangement of the material does not differ from that usually adopted, beginning with the anatomy of the pelvis and the process of ovulation, and proceeding in the consideration of the various phenomena which lead to the act of parturition and accompany and follow it. The style is clear, and the matter judiciously arranged. The type used in the composition of the work is too small, except for those blessed with very sound eyes, which is an objection of somewhat serious magnitude in these days when so many suffer from visual defects. The pages are, however, well printed, and the illustrations carefully reproduced.

Diseases of the Digestive Organs in Infancy and in Childhood. By Louis Starr, M. D., with Illustrations. 1 vol., 8vo., pp. 387. Price $2.50. Phila.: P. Blakiston, Son & Co., 1886.

Every physician is aware how large a proportion of the diseases of infancy expend their violence on the digestive organs or involve their functions. In choosing therefore these diseases as the subject of a monograph, the author of this work has selected a subject in which all practitioners are interested.

After some general instruction as to the investigation of disease in infancy, he begins with affections of the mouth and throat; from these passing to affections of the stomach and intestines. That peculiar dyscrasia, tabes mesenterica, then comes up for consideration. A chapter is devoted to disturbances of the liver, and another to those of the peritoneum. The volume closes with about forty pages explaining the general management of infants and children with reference to the important factors of feeding, bathing. clothing, sleep, and exercise.

There is one full page colored plate of the appearance of the tongue, and a number of illustrations. The material of the work has evidently been drawn from original and careful observation on a wide scale, and this gives it a freshness and value which will be appreciated by all readers.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

AN UNUSUAL SEQUELA OF OVARIOTOMY.

To the Clinical Society of London, (March 13,) Mr. R. Barwell read a paper on a case. At the latter end of last October, he removed the left ovary of an unmarried woman, aged 29. The local results were perfect; but certain sequelæ ensued which had not hitherto been recorded, but, on questioning other surgeons, Mr. Barwell found the event not to be isolated, and notably that Dr. Keith, Mr. Thornton, Mr. Dent, Dr. Bantock, and others, had met with a like complication. The patient was of fair complexion, and mobile temperament. She came into Charing Cross Hospital, and it was agreed that ovariotomy should be performed. On October 28th, Mr. Barwell removed the left ovary, first withdrawing twenty-three pints of fluid; the pedicle was tied with silk, and allowed to fall back into the abdomen. The usual mode of suture was employed. During the three subsequent days, menstruation recurred, and some hæmaturia was observed; it then ceased. On the third day, the thermometer stood for two hours at 102.4°, but, with this exception, she never had a temperature worthy of notice. The deep sutures were removed after forty-eight hours. The abdominal wound was healed on November 2d; there was hardly any tenderness in the left groin, or elsewhere. The patient, who was naturally very docile and amenable, showed, on November 3d, a contradictory and aggressive temper; on the 5th (eighth day of operation) this had developed into insanity. On November 7th, she was so violent that she had to be secured, and this could only be effected by giving a little chloroform. A subcutaneous injection of four minims of solution of morphia only calmed her for three hours. On the 21st, with various phases of comparative violence and calm, but with incessant talking, the patient continued entirely insane, sleeping only in short snatches about two hours out of the twenty-four until the 19th. She then began to show signs of amelioration, especially in saying that she knew she was mad. On the 21st, Mr. Barwell ordered an ice-bag to the head. After this she slept more, and gradually improved. On the 28th, she would be pronounced sane. During all December she was well enough to take walks, but was, for various reasons, kept under supervision till December 29th, when she was discharged in perfect mental and bodily health. In spite of several attacks of violence, and of struggling, the abdominal cicatrix had held well, and there was no sign of hernia; nevertheless, it was thought prudent to provide her

with a belt. Mr. Barwell remarked that several views might be taken of this case:

1. There might have been hereditary tendency to insanity.

2. Insanity might follow any of the major operations, ovariotomy not more than any other.

3. It was the result of disturbance of the urinary organs (kidney).

4. It was the result of disturbance of the generative organs.

5. It was mere coincidence.

On these views he made the following comment:

1. Great pains were taken to find any trace of mental disturbance in the patient's family. None could be discovered. Her father had died of cerebral apoplexy at an advanced age.

2. If insanity were an occasional sequela of surgical operations, the matter was not mentioned in surgical writings.

3. The amount of blood lost by the kidney, if any, was insufficient to produce grave effects. Hæmaturia was not uncommon after intraperitonal operations performed under a carbolic spray.

4. Although disturbance of the generative organs appeared, at first sight, to offer the easiest explanation, in this case there were none of the erotic symptoms usually associated with abnormal states of that system. Perhaps some might see an analogy between puerperal insanity and mental disturbance in this case.

5. Mere coincidence might be justly considered the best way of accounting for insanity thus following ovariotomy if this were an isolated instance, but Mr. Barwell was acquainted with several other examples.

Thus, Dr. Keith had had one case (after hysterectomy); Mr. Thornton, two (ovariotomy and hysterectomy); there had been a case at St. Thomas's Hospital, and one had been noted by Mr. Dent. Thus, mere coincidence would not account for the circumstances which it appeared desirable should be known in the profession.

The President remembered that Mr. Lawson Tait had read a paper some time ago, in which symptoms of mania had occurred during convalescence from ovariotomy. He himself had seen mania occur in two cases after ovariotomy, which did well surgically; and although in his experience of general surgical cases it was rare, he could not help thinking there was some connection between it and the operation of ovariotomy. In these cases there was no kidney mischief.

Mr. Doran mentioned the case of a young married woman who had had both ovaries removed for chronic inflammatory disease; she had previously presented no mental symptoms, but was the subject of an attack of mania a few weeks after the operation; she was still deranged. Insanity connected with organic disease of the genital organs was not necessarily of the nymphomania type.

Mr. Meredith thought the cases not quite so rare as Mr. Barwell had concluded them to be. He had seen symptoms of insanity come on two weeks after the operation; but once, for four weeks after the removal of a large tumor, weighing 70 lbs., from a single woman, aged 54, no bad symptoms resulted, and then the patient was seized suddenly with acute melancholia; she was apathetic, but not really violent. The symptoms lasted for two months without intermission, and then disappeared suddenly, and she had remained quite well ever since (four years). There were no urinary symptoms, and no hereditary tendency. He had seen acute mania following amputation of the breast.

Dr. Edis said that patients were often very nervous, and subjected to high nerve-tension, before the operation. In many, the nervous system was immobile, and easily gave way under such provocation. He remembered the case of a farmer's wife who was hypochondriacal, with oval face, dark skin, weighing her words, as if with a sinister meaning, who, after the operation of ovariotomy, developed symptoms of melancholia. She became quite well, the symptoms lasting for ten days. He thought the symptoms of insanity were not so unusual as one might imagine.

Mr. Benham thought these cases might be parallel to those of puerperal insanity, which he had never seen well explained.

Dr. Blandford was inclined to think there were many circumstances connected with ovariotomy which might give rise to mental symptoms. The patient had before her mind, for some time before the operation, what she had to undergo, not taking much food, and her bowels locked up with opium, and opium had a peculiar effect upon some persons of keeping them awake. He did not think the mania had anything to do with urinary trouble. The case was one of genuine mania.

Mr. Barwell, in reply, said that, although he might not have been exactly correct in his description of the mania, he hoped its occurrence was unusual. His object had been fully achieved if he had succeeded in directing attention to the matter. Every operation, of course, must disturb the thoughts for a little time; but, in simple cases of this

description, the patients recovered with remarkable ease. He thought the case of Dr. Edis was hardly comparable with his, as that case was probably half mad before the operation was performed.

BENZOATE OF SODIUM IN CHOLERA INFANTUM.

The fact is well known that during the summer cholera infantum appears almost as an epidemic in our large cities. Dr. Guaita (*Allg. Wien. Med. Ztg.*, 21, 1886), has made a special study of this disease, and come to the conclusion that it is due to a special microbe, which in some way enters the system and then becomes pathogenic, if the conditions are favorable to its development. This is shown by the fact that the summer-complaint of children, especially of those who in consequence of their having been nourished by the milk from the breast of their mother or wet-nurse possess a healthier alimentary canal, is often easily controlled, if treated correctly at the very start.

Guaita's observations refer to 53 cases at the age from six months to two years; 35 had been sick for from 24 to 30 hours; 18 for 6 to 14 days. In the first recovery occurred within from 4 to 8 days; in the last in average within 21 days: no death. The so successful treatment consisted in the following:

First a mild laxative (calomel, jalapa); then from 64 to 96 grains of benzoate of sodium in 4 oz. of water per day; the third day again a laxative (manna, magnesia), then once more benzoate of sodium in same doses, the size of the latter being regulated more by the age of the child than by the urgency of the symptoms. Already the second day an improvement is noticeable in the alvine discharges; the fœtid odor ceases, also the vomiting. During the treatment no food whatever must be administered; only a little lemonade and good wine. Milk and beef-tea are specially forbidden, as cow's milk ferments too easily in the stomach; infants may be given the breast four times in 24 hours.

Unless further observations prove the contrary, the omission of all food may perhaps have as much to do with bringing about the favorable result as the remedy mentioned, benzoate of sodium; for of late years we have been in the habit of adopting the same stringent measures, and have obtained a uniformly good result, confining ourselves as regards medication simply to laxatives—sulphate of sodium—and mild astringents. Still, the fatality of cholera infantum in large cities during the summer is so great, that any remedy promising the least success should be welcome. It may be well to give the benzoate of sodium a more extended trial.

INSOMNIA IN CHILDREN.

Children, for some reason or other, often suffer with sleeplessness. Opium, as a rule, does not act kindly on them; they either become very drowsy or are troubled with hallucinations.

Dr. Illingworth has tried a number of remedies to test their hypnotic effect in children. He gives the first place to hydrate of chloral. But whenever the insomnia is the first symptom of the basillar meningitis so frequently met with in the very young, he obtained the best results from the administration of corrosive sublimate in conjunction with iodide of potash and hydrate of chloral. The formula recommended by him is as follows:

℞.	Liquor hydrarg. bichlorid..	8.0.
	Potass. iodat.,	0.6–1.0.
	Chloral hydrat.,	1.0.
	Aq. destillatæ,	45.0.
	Syrup. simplicis,	15.0.

M. S.—A teaspoonful in water every two hours.

COLORLESS TINCTURE OF IODINE.

Dr. V. Favre publishes in the *Pharmaceut. Post* the following recipe for a uniform non-decomposing colorless tincture of iodine:

℞.	Ammonii iodat.,	8.0.
	Iodoformi,	2.0.
	Liq. ammon. caust.,	2.0.
	Alcohol (90 %),	98.0. M.

Iodoform and iodide of ammonium are first dissolved in the alcohol, and aq. ammoniæ added, and the whole are exposed to the daylight for ten days. The tincture becomes colorless, but to prevent decomposition entirely, there must be a superfluous quantity of the ammonia.

Notes and Comments.

Excision of the Pylorus.

A case of resection of the pylorus, terminating fatally, is related by Dr. Van Sterson in the *Weekblad* of January 2. He remarks that he has mentioned it intentionally, not to discourage or deter others from the operation; but from his own conviction that, when local and general circumstances are favorable, he believes the operation to be distinctly indicated. In the case mentioned, the pa-

tient died from want of strength to resist the shock of the operation, having previously suffered from vomiting and diarrhœa. The patient was a woman, aged 51. When put under chloroform, the narcosis was calm and regular. A tumor was found in the pyloric region; there were no adhesions and no ulceration. The tumor affected the pylorus alone, and was very hard; on microscopic examination, it appeared to consist of a "tubular carcinoma," or "non-typical adenoma." After the tumor had been cut out, the stomach was found to be perfectly empty, a sponge, which had been introduced, returning quite clean. The mucous membrane of the stomach was not ulcerated. The cut ends of the duodenum and the stomach were very carefully sutured together; a couple of camphorated ether injections were given to the patient, and she was laid in a warm bed. She roused sufficiently to be able to answer questions, and to state that she felt no pain, but her pulse was scarcely perceptible. Camphorated ether injections were continued every quarter of an hour, but in two hours and a half death occurred. There had been no particular difficulty in the operation, and no subsequent pain; but the patient had not sufficient vitality to survive the shock.

Scarlatina in Utero.

Dr. Wilson Saffin, of Carthage, O., reports the following case in the *Med. Record:*

A lady of good general health, who had had scarlatina when young, was delivered of a male child, labor being normal and of short duration. During the two weeks preceding delivery she was in constant attendance upon her older child, who was suffering from malignant scarlet fever, and who died three days after her confinement. During the first week of this child's illness the mother contracted a very sore throat, characterized by intense hyperæmia and involvement of the submaxillary glands. Immediately after delivery, upon examination of the child, the characteristic rash of scarlatina was observed. The disease was well marked, and ran a course of nine days. Desquamation occurred on the fifth day, and was as natural and well marked in large and small flakes as in any other and older child. The temperature ran from 100° to 104°, and was highest on the third day of life. Considerable nausea and diarrhœa were manifested on the third and fourth days, but no other symptoms than those mentioned presented themselves. The mother and child both made a good recovery, although the woman was confined in the same room in which her other child died. Dr. Saffin diagnosed the case as one of scarlatina in utero, as the rash was fully developed at birth.

Neurectomy.

Mr. Bishop showed to a recent meeting of the Manchester (England) Medical Society a case of intractable neuralgia of the intercostal nerve, following traumatism, which had been cured by neurectomy. A woman, aged 34, fell through a man-hole ten years ago, and ever since had noticed a lump in her right breast. In 1884, it began to be painful, and it was removed at her request in March. As soon as the small wound healed, neuralgic pain in the breast was complained of, and, the scar being somewhat depressed, this was freed. Pain still continued; the breast became hot and heavy, subjectively; and later, herpes, rapidly ulcerating, showed itself upon it. Various remedies were used, but without result. In consequence of her persistent demands, the whole breast was removed in September, 1885. Still the pain continued, and the herpes, along, and on each side of, the scar, became worse. General remedies were tried afresh, whilst anodyne applications were freely used externally, but no relief was obtained; the actual cautery was also used, but without result. In February, 1886, the fourth intercostal nerve was cut down upon in the posterior axillary line, and half an inch removed. The nerve was found outside the external intercostal muscle; it was in a state of neuritis. On recovery from chloroform, the pain had disappeared, and had not, on April 14th, returned. The patient was increasing in weight, and was in very good spirits.

Palliative Treatment of Uterine Cancer.

Dr. Gaches Sarrante, in an article on the treatment of uterine cancer (*Nouvelles Arch. d. Obstet. et de Gynec.*, March 25, 1886), thus summarizes the results of his experience:

In cancer of the uterus, frequent dressing with liquids, powders, or other antiseptic agents, presents the following advantages:

1. When regularly applied, they suppress absolutely the hemorrhages, even when rebellious.

2. They modify the nature of the lesion by removing the putrescent products which form on its surface, and give it the appearance of a healthy sore.

3. At first they calm the pains, which later return with increased intensity, finally to cease definitely.

4. They prevent the absorption of infectious products, and thereby greatly improve the general health of the patient.

5. They moderate the extension of the lesion, and prevent extension by contiguity to the vagina and bladder.

6. Finally, they permit the patient to live the life of the world at large, and, so to speak, to dissimulate her malady.

Fever.

Before the Medical Society of London, Mr. Browning read a paper on this subject. He commenced with a brief review of the opinions held by Cullen, Watson, Addison, and Alison. Admitting that in typhus and typhoid there was little difficulty in making a differential diagnosis, yet the reader of the paper alleged that there was a certain number of cases in which the characteristics of each were not so clearly marked, and diagnosis became a difficulty. He put two questions:

1. Whether it was possible to have typhus fever without a rash of any kind; and if so, did it often occur?

2. Whether there was any specific form of fever known as typhoid which was not enteric, that is, Peyer's patches unaffected?

His experience inclined him to give an affirmative answer to the first question; and he believed he had seen cases with well marked features of typhus, the rash being absent. He felt less able to give a definite reply to the second query.

Hæmorrhagic Glaucoma Treated by Trephining.

Before the British Ophthalmological Society, Mr. Spencer Watson showed drawings from a case of hæmorrhagic glaucoma, in a man aged 64; the sclerotic was trephined, and the choroid was accidentally perforated; the tension became normal, and so remained for three months, but without any improvement in vision. The tension, however, again rose, so that the result was most unsatisfactory. Dr. W. A. Brailey said that, in those cases where pain was severe and vision hopelessly lost, the best treatment was to stretch the supratrochlear nerve. Mr. McHardy thought the case showed conclusively that the operation of trephining was liable to fail entirely to relieve the distressing tension in these cases. He had been astonished by the ease with which the supratrochlear nerve could be found in the living subject. Mr. Edgar Browne had stretched the supratrochlear nerve in two cases, without noticing any diminution in tension. Mr. Spencer Watson said, in reply, that since the operation pain had not recurred.

A Carbuncle Cured by a Gonorrhœa.

Dr. F. N. Smith, of Allentown, N. Y., writes to the *Med. Record:* "I had been treating a young man for boils and carbuncles some ten days, when, on one day, a large carbuncle on the back of the neck was just on its way toward maturation, acutely painful, and preventing all work—my patient was a railroad bridge-builder. The next day, very early in the morning, he came to me, saying that his carbuncle was about well, but that he had a private disease, just showing itself that morning, and would like that attended to now. On examination I found a well marked case of gonorrhœa. He had no more trouble with carbuncles from that day; the specific disease passed away in due time. There is no doubt that the occurrence of the gonorrhœa had the effect of arresting at once the progress of the carbuncular inflammation."

Mitral Stenosis in Labor.

Before the Obstetrical Society of London, Dr. George Coates describes this case. The patient was aged 22, and had suffered from rheumatic fever, but had no suspicion of heart-disease. She had suffered from anæmia and breathlessness. The labor began on October 23d, 1885. On the 24th she felt faint several times. On examining the heart, a presystolic murmur at the apex was detected. In the evening the os uteri was fully dilated, and she showed signs of exhaustion. The forceps was put on and delivery accomplished. The pulse varied in the next two hours from 180 to 130, then it fell to 108, and in the morning to 76. The murmur disappeared on and after the tenth day. On November 13th she had a rigor, and sharp pain in the left breast and one elbow. She was treated for acute rheumatism, and recovered. The murmur quite disappeared.

Destruction of Microbes by Heat.

At a meeting of the Société de Médecine Publique et d'Hygiène Professionelle de Paris, Dr. Grancher communicated the result of his experiments on the resistance offered by microbes to the heat of disinfecting stoves. They are as follows: The moist vapor stove of MM. Geneste and Hersche is an excellent disinfecting apparatus. With this stove a temperature of 106° Cent. is

easily obtained; microbes are undoubtedly destroyed, though they be imbedded in mattresses. The dry-air stove, of the same manufacturers, is not so completely disinfecting as their moist-vapor stove. With this apparatus the bacteria of charbon, its spores, the tyrothrix scabiei, and bacillus subtilus, are not destroyed. The hot-air stove at the Hôpital des Enfants Malades is a still more imperfect disinfecting stove.

A Case of Median Nerve-Suturing.

To the New York Neurological Society, Dr. Fraser C. Fuller presented a man who, two years and a half ago, sustained a glass-cut wound of the lower forearm, resulting in complete division of the median nerve and a part of the tendons of the flexor sublimis. The nerve was sutured with three small strands of catgut a few hours after the injury. The tendons were also united. The operation and dressing was absolutely antiseptic, and primary union took place. At the time of the operation there was complete cutaneous anæsthesia of the region supplied by the nerve. After several months, sensation slowly returned, and a year and a half after the operation it was perfect. Power in the small muscles of the affected hand had not entirely returned.

Morphine Hypodermically in the Eclampsia of Children.

Dr. M. Leventener, of Constantinople (*Centbl. f. d. ges. Ther.*, xii., 1885), has employed subcutaneous injections of morphine with marked success in a case of eclampsia in a child four months old, after the usual remedies had been tried and failed. He gave the first hypodermic when the convulsions had already continued for over twenty-four hours, the second was given two hours later, the third six hours, and the fourth ten hours later. In each injection he employed one-forty-eighth of a grain of morphine. The first two injections were followed by the cessation of the convulsions for a prolonged period. The hypodermics had to be repeated three times afterward, and the child made a good and rapid recovery.

Diet in Albuminuria.

After passing in review the principal theories which have been given regarding the pathogenesis of albuminuria, Nollet offers the following conclusions:

1. Milk diet has as yet given the best results in the treatment of albuminuria.
2. This method is not applicable to all forms, and if too prolonged may produce serious inconveniences for the patient.
3. The albuminuric should avoid large meals, eating frequently, but little at a time.
4. Individual susceptibility must determine the sorts of animal food least injurious to the patient.
5. Fish appears to favor the passage of albumen into the urine.

Effect of Alum Gargles upon the Teeth.

From the *Journal Am. Med. Ass.* we learn that M. Young prescribed a gargle containing a small proportion of alum for a woman suffering from chronic pharyngitis, with catarrh of the middle ear. The patient, finding relief, continued its use for some three weeks. But perceiving that, at meals, her teeth began to crumble into little pieces, she consulted her dentist, who considered it due to the alum gargle, as when the enamel is removed from the teeth, the alum breaks down the dentine. To prevent this, it is best, immediately after using the alum gargle, to wash the mouth out with a solution of bicarbonate of soda, or an alkaline water.

Removal of Foreign Bodies from the Ear.

In the *Brit. Med. Jour.*, Dr. J. H. Granshaw suggests the following method for removing foreign bodies from the ear:

"A large syringe holding four or six ounces, a basin of rain-water soap-suds as hot as can be borne, and a steady hand, are all that is required. With this simple apparatus, I have, over and over again, removed cherry-stones, beads, buttons, slate-pencils, etc., from the ears of children, and always without pain; nor has it ever failed me. The injection of a few syringefuls will generally suffice."

Bacteriotherapy.

Dr. Salama reports another case of advanced pulmonary phthisis treated according to Cantani's method, by inhalations of bacterium termo. Within five days an improvement was noted, the fever was less pronounced, and the expectoration was diminished in quantity, and contained a smaller number of tubercle bacilli. In two weeks the bacilli had wholly disappeared from the sputa, and the patient began to increase in weight and in general health.

Carbolic Acid in Freckles.

Halkins (*Annales Médico-Chirurgicales de Liege*, January, 1886) has had good results

in freckles from, after bathing the skin, drying it completely, and stretching it with the left hand, applying to the freckles a thin film of acid, which is allowed to dry. In a few days the spots are more noticeable, but in a week a flake of skin is detached, leaving a rose-colored spot, which soon resumes a natural color.

Sassafras Oil in Neuralgia.

Dr. Thos. J. Miller (*Virginia Medical Monthly*) finds that sassafras oil gives good results in neuralgia. He gives it in soda water. He has also found it available as a substitute for veratrum viride.

Correspondence.

"On Emission of Semen as a Means of Diagnosis of Death by Hanging."

Eds. Med. and Surg. Reporter:

In recognition of your journal being one of the most influential, also most widely circulated in the world, I feel as if it is trespassing on your valuable space to offer additional testimony in support of Dr. Hamlin's paper on the above subject, and to answer Dr. Colvin's *insinuations*.

Having long since passed my majority in the practice of medicine and surgery, seeing my name paraded in the journals has very little effect on me. Now to the point. In the discussion of any subject, medical or scientific, we cannot go behind the facts. I stated that the late Dr. J. E. Bennett had observed the emission of semen in every case of hanging at U. S. jail at Fort Smith prior to 1880, that is, during the long period he was the physician of the jail, and since that time my observation confirmed his statement. There were eight criminals sentenced to be executed on the 23d day of last April; six had a commutation of sentence, and the remaining two were executed.

Case 1. A white man; crime, murder, of robust health, neck broken, there was emission. I gave the specimen to Dr. I. W. Buell, Asst. Surg. of U. S. Army, for microscopic examination, and submit his report to me:

"At Home, 4, 24, '86.

"Dr. G. W. Smith—*Dear Doctor:* The microscopic examination of the specimen submitted to me yesterday by yourself proves beyond doubt that it is human semen. The spermatozoa were very numerous and active, and retained their activity at the time the last examination was made, which was twelve hours after the specimen came into my possession. Very truly yours,

"I. W. B."

Case 2 was a robust negro. Crime, murdering his wife. Neck broken; had no emission. Why? Both testicles were atrophied, and on dissection of the testicles found no semen or other fluid in them. His wife had no children. He had yellow atrophy of both testicles.

On 23d of July next another execution will take place. I will report to you the full particulars in this case.

Geo. W. Smith, M. D.

Fort Smith, Ark.

News and Miscellany.

Ohio State Medical Society.

The forty-first annual meeting of the Ohio State Medical Society will be held at Akron, Ohio, June 2d, 3d, and 4th, 1886.

OFFICERS.

President, Wm. Morrow Beach, London. *Vice-presidents*, H. Z. Gill, Cleveland; H. R. Kelly, Galion; Thomas McEbright, Akron; J. D. Robison, Wooster. *Secretary*, G. A. Collamore, Toledo. *Assistant Secretary*, E. C. Brush, Zanesville. *Treasurer and Librarian*, T. W. Jones, Columbus.

Committee of Arrangements, Thomas McEbright, H. M. Fisher, E. W. Howard, C. R. Merriman, Daniel A. Scott.

ORDER OF BUSINESS.

The order of business for each session will be:

1. Call to order.
2. Reading of minutes.
3. Report of Committee of Arrangements. (On first day.)
4. President's address. (Afternoon of second day.)
5. Election of officers. (Afternoon of second day.)
6. Selection of a place for the next meeting. (Afternoon of second day.)
7. Business which requires early consideration.
8. Annual reports (on first day) of
   a Treasurer and Librarian.
   b Secretary.
9. Reports of Standing Committees:
   a Committee on Admissions and Medical Societies.
   b Committee on Finance.
   c Committee on Publication.
   d Committee on Legislation.

e Committee on Ethics.

10. Reports of Special Committees: (on first day.)

a Committee on State Board of Medical Examiners Bill.

b Committee on General Collective Investigation of Disease.

11. Reports from Delegates to the American Medical Association and other Societies. (On first day.)

12. Written Communications on Medical Subjects.

13. Oral Communications.

14. New Business.

15. Unfinished and Miscellaneous Business.

16. Adjournment.

The following written communications are expected:

a "Report of a Case (with Treatment) of Posterior Torticollis:" H. Z. Gill, Cleveland.

b "The Importance of Early Operations in Surgical Injuries:" R. Harvey Reed, Mansfield.

c "Vicarious Menstruation:" W. J. Jenkins, Plain City.

d "On the Close Relation and Probable Identity between Scarlatina and Diphtheria; with Pseudo-Membranous Croup considered:" A. Hurd, Findlay.

e "The Present Aspect of the Treatment of Vesical Calculus:" N. P. Dandridge, Cincinnati.

f "Intestinal Antisepsis:" D. N. Kinsman, Columbus.

g "Some Practical Observations in Obstetrics:" Frank D. Bain, Kenton.

h "Progress in the Treatment of Epithelioma:" B. M. Ricketts, Cincinnati.

i "Some Cases of Abdominal Section:" C. A. L. Reed, Hamilton.

j "Selected Cases of Laparotomy:" Dudley P. Allen, Cleveland.

k "Conservatism of Symptoms in Disease:" John W. Russell, Mt. Vernon.

l A Paper by E. Williams, Cincinnati.

m "Therapeutic Uses of Codeia:" Starling Loving, Columbus.

n "Cardiac Complications of Bright's Disease:" J. T. Whittaker, Cincinnati.

o "Treatment of Malignant Carbuncle:" N. Gay, Columbus.

p "Dietetics in Idiopathic Fevers:" H. J. Herrick, Cleveland.

q "The Surgery of Diabetics:" P. S. Conner, Cincinnati.

r "Dressing of Injured and Amputated Fingers:" J. T. Woods, Toledo.

s "The Alcohol Question:" Wm. B. Davis, Cincinnati.

t "Diseases of the Skin occurring in the Subjects of Gout:" W. T. Corlett, Cleveland.

u "Common Errors (theoretical and practical), relating to Insanity:" Orpheus Everts, College Hill.

v "Phosphor-Necrosis:" W. C. Jacobs, Akron.

w "The Temperature of the Body in Health and Disease:" H. Hathaway, Toledo.

x "Sun Strokes: Walter A. Dun, Cincinnati.

y "A Partial Study of the Statistics of the Insane in Ohio, covering a Period of Twenty-five Years:" E. J. Wilson, Columbus.

z "The Visual Field as a Diagnostic Symptom:" B. L. Millikin, Cleveland.

aa "Report on Trephining the Spine:" and "The Radical Cure for Hernia:" A. W. Ridenour, Massillon.

bb "Relation of the Physician to the Public:" L. Slusser, Canton.

cc "The Effects of Food in Health and Disease:" J. W. Shively, Kent.

dd "Treatment of Purulent Inflammation of the Middle Ear:" A. R. Baker, Cleveland.

xx Volunteer Papers.

The sessions of the Society will be held in the Business Parlors of the Universalist Church on Mill St.; first Session at 2:00 P. M., Wednesday, June 2d.

HOTELS.

The following hotel rates per day are offered: Buchtel, $2.50 and $2.00; Empire, $2.00; Continental and Windsor, each, $1.50.

RAIROADS.

In order to obtain return tickets at one-third the lowest unlimited fare, members or delegates must procure the necessary certificates from the Secretary, before they leave home. In making application for certificates the route proposed to be taken should be specified. G. A. COLLAMORE, M. D.,

Toledo, Ohio. *Secretary.*

Medical Society of New Jersey.

The next annual meeting of the Medical Society of New Jersey will be held in the Girt House, Sea Girt, on Tuesday and Wednesday, June 8th and 9th, 1886, commencing at 4 o'clock p. m., on Tuesday.

Committee on Organization will meet in the drawing-room at 3 o'clock p. m. Delegates are requested to present their credentials at that time.

Treasurers of district societies are requested to send the amount of dues of their respective societies to Dr. W. W. L. Phillips, Trenton, on or before the 7th of June. The annual assessment is $1.50 per capita.

OFFICERS.

President, Joseph Parrish, M. D. Burlington; *First Vice-President*, Charles J. Kipp, M. D., Newark; *Second Vice-President*, John W. Ward, M. D., Trenton; *Third Vice-President*, H. Genet Taylor, Camden; *Corresponding Secretary*, William Elmer, Jr., M. D., Trenton; *Recording Secretary*, William Pierson, M. D., Orange; *Treasurer*, W. W. L. Phillips, M. D., Trenton; *Standing Committee*, T. J. Smith, M. D., Bridgeton; E. J. Marsh, M. D., Paterson; D. C. English, M. D., New Brunswick.

PROGRAMME FOR TUESDAY.

Four o'clock p. m.

Prayer by Rev. Dr. Brown, of Manasquan.

Report of Committee on Credentials, Secretary, Chairman.

Calling roll.

Report of Committee on Arrangements, D. McLean Forman, M. D., Chairman.

Reading of Minutes of last annual meeting.

Report of Committee on Business, H. R. Baldwin, Chairman.

Any business which requires early consideration may be introduced.

Report of Committee on Ethics and Judicial Business.

Announcement of Committees by the President.

Adjournment at 6:30 o'clock.

(The several delegations are requested to report to the Secretary as early in the afternoon as convenient, the name of their member to serve on the Nominating Committee.)

Tuesday Evening 7:30 o'clock.

Annual address by the President, Joseph Parrish, M. D., "The Geography of Malaria."

Report of Standing Committee, T. J. Smith, M. D., Chairman. (Five minutes will be allowed to each delegate for remarks upon the same.)

Report of Treasurer, W. W. L. Phillips, M. D.

Report of Corresponding Secretary, Wm. Elmer, Jr., M. D.

Report of Committee on Honorary Membership and Honorary Degree of Doctor of Medicine.

Receiving and acting upon applications for honorary membership and honorary degree.

Discussion upon subject suggested at previous meeting.

"The result of the use of the Muriate of Cocaine in Ophthalmic Surgery, and also in general practice, as developed by the experience of individual practitioners."

Adjournment.

PROGRAMME FOR WEDNESDAY.

Nine o'clock a. m.

Report of Committee on Treasurer's Accounts, John Ryerson, M. D., Chairman.

Report of Delegates to, and Reception of Delegates from Corresponding Societies.

Essay—H. Genet Taylor, M. D., Third Vice-president, "Medical Education."

Essay—W. K. Newton, M. D., Paterson, "The Relations of the Physicians to the State."

Discussion upon the Report of Committee on Education. The report was published in the Transactions for 1885.

Report of Committee on Lunacy, Dr. Parrish, Chairman.

Report of Committee on "Fellows' Prize Essay," P. C. Barker, M. D., Chairman.

Investigation of By-Laws and Communications from District Societies.

Reading of such papers as approved by the Business Committee.

Paper by G. H. Balleray, M. D., Paterson, "Abdominal Surgery."

Reports of interesting cases.

Intermission from 1 to 3 o'clock, for dinner.

Three o'clock p. m.

Report of Nominating Committee.

Election of officers.

Miscellaneous business.

Acting upon amendment to by-laws.

As the hotel at Spring Lake will not be opened in time for the meeting, the Committee of Arrangements has arranged to hold the meeting at Sea Girt. The proprietor of the Sea Girt House, Mr. Boldt, has agreed to have the hotel in complete readiness for the accommodation of all who may attend. The hotel will accommodate several hundred guests.

Every effort on the part of the Committee of Arrangements has been made to make the meeting a pleasant and profitable one, and it is hoped that its efforts may be rewarded by a large attendance.

Excursion tickets over the various railroads may be procured at the principal railroad stations.

The delegates (corresponding included) are invited to bring their families with them. The members of the profession throughout the State are cordially invited to attend the

meeting, and also to bring their families with them.

D. McLean Forman,
Robert Laird,
Henry Mitchell,
Committee of Arrangements.
Wm. Pierson, *Secretary.*

Orange, N. J., May 8, 1886.

Officers of the International Medical Congress.

The Executive Committee of the International Congress, we are informed ,have finally elected the following officers for the Washington Congress :

President—N. S. Davis, of Chicago.

Vice-Presidents—W. O. Baldwin, of Montgomery, Ala.; William Brodie, of Detroit; W. W. Dawson, of Cincinnati; E. M. Moore, of Rochester, N. Y.; T. G. Richardson, of New Orleans; L. A. Sayre, of New York; J. M. Toner, of Washington; the President of the American Medical Association, the Surgeon-General United States Army, Surgeon-General United States Navy, Supervising-General Marine Hospital Service.

Secretary-General—J. B. S. Hamilton, U. S. Marine Hospital Service.

Treasurer—E. S. F. Arnold, of New York.

Chairman Finance Committee—Frederick S. Dennis, of New York.

PRESIDENTS OF SECTIONS :

Medicine—A. B. Arnold, of Baltimore.

Surgery—William T. Briggs, of Nashville.

Military and Naval Surgery—H. H. Smith, of Philadelphia.

Obstetrics—Delaskie Miller, of Chicago.

Gynecology—James H. Harrison, of University of Virginia.

Anatomy—William H. Pancoast, of Philadelphia.

Physiology — J. H. Callender, of Nashville.

Pathology — A. B. Palmer, of Ann Arbor.

Diseases of Children—J. Lewis Smith, of New York.

Ophthalmology—E. Williams, of Cincinnati.

Otology—S. J. Jones, of Chicago.

Laryngology—W. H. Daly, of Pittsburgh.

Dermatology and Syphilis—A. R. Robinson, of New York.

Hygiene—Joseph Jones, of New Orleans.

Collective Investigation, etc.—H. O. Marcy, of Boston.

Nervous Diseases—John P. Gray, of Utica.

Dental and Oral Surgery—J. Taft, of Cincinnati.

Civilization and the Size of the Human Cranium.

In the course of a paper recently read before the Grant College Medical Society at Bombay by Surgeon D. M. Parakh, I. M. D., in which an account was given of the midwifery work done in the only obstetric hospital in Bombay for native women, the author remarked that from measurement soon after birth of the transverse, fronto-mental, and antero-posterior diameter of the heads of native children, the conclusion was that the greatest measurements were in the following order as to race :

1. European.
2. Persian or Iranee Parsee, *i. e.*, a modern Persian professing the old Zoroastrian religion, and just arrived from Persia.
3. Parsee.
4. Goanese.
5. Mahommedans, Hindoos, and native Christians.

From what he had seen in practice, his impression was that owing to the increasing civilization of the masses in India, the human cranium is gradually increasing in size, the pelves of women unfortunately not undergoing a corresponding increase in capacity. This is particularly the case among the Parsees, who have, under the British rule, suddenly emerged from a semi-barbarous life into a life of great mental activity, the males (even now) being about a generation or two ahead of the women in that respect. Hence British rule, while it has improved the head and heart and purse of the coming Parsee race, has entailed greater suffering on the parturient woman. In saying so, Mr. Parakh was not, he stated, unmindful of other evils of civilization which make parturition difficult. The average weight of the children at birth was 5.85 pounds. The maximum was 8.75 pounds; the minimum 3.75 pounds. The heaviest children were in precisely the same order as to race as mentioned above in the case of head measurements.

Debore's "Cramming" or "Forced Feeding" System.

In the *Chemist and Druggist* we find a description of this treatment as practiced on five phthisical patients. In this "cramming" system a stomach-tube is employed should the patient have intense repugnance to food; and this had to be done in some of Dr. Kurloff's cases. The food which he administered was a mixture of milk and pulverized meat, from which all the liquid portion had been expressed. The amount of food given af-

forded in the minimum 54 grammes of nitrogen (equivalent to 3½ pounds of butcher's meat), and in the maximum 80 grammes of nitrogen (equal to 5¼ pounds of butcher's meat). This was given daily, and the immediate effects were an increase of excreted nitrogen from 9 and 16 to 34 and 56 grammes per day, due to increased breaking up of the albuminous constituents of the body. With this breaking up there was an increase in assimilation of nitrogen to the extent of threefold, weight increased 1 pound per day, and the appetite (which previously was almost *nil*) improved so remarkably that the patients, after a week of the treatment, eagerly partook of ordinary hospital diet to excess of the usual allowance. So far the feeding results were most satisfactory, but there have to be recorded the facts that in three consumptives the expectoration diminished, diarrhœa and night sweats ceased, and some of the patients so improved in general health as to be able to return to their every-day work.

Faith-Healing.

Rev. Dr. Buckley, editor of the *Methodist Christian Advocate*, has a long and exhaustive article on "Faith-healing," in the June *Century*, which concludes as follows: "The faith-healers represent God as interfering constantly, not by cause and effect in the order of nature, but affecting the result directly. Their want of superiority to those who are not Christians, but use either false pretenses or natural laws, and their inferiority to Christ and the apostles, condemn their pretensions. Nor does it avail them to say, 'Christ would not come down from the cross when taunted by unbelievers.' They might perhaps with propriety refuse a test for *the test's sake*, though Elijah forced one. But in a close observation of their works the radical difference between them and those who they say have no divine help should be manifest. Some of them affirm that the Mormons, Newton, and others, do their mighty works by the aid of devils. If so, since casting out devils was a miracle-working power of a very low grade, it is wonderful that none of these persons have been able to cast out the devils from any of the great number who are working in this way, and thus demonstrate their superiority, as the apostles vindicated their claims against Simon the sorcerer, and others.

"Faith-cure, technically so called, as now held by many Protestants, is a pitiable superstition, dangerous in its final effects.

"It may be asked, what harm can result from allowing persons to believe in 'faith-healing?' Very great indeed. Its tendency is to produce an effeminate type of character which shrinks from any pain, and to concentrate attention upon self and its sensations. It sets up false grounds for determining whether a person is or is not in the favor of God. It opens the door to every superstition, such as attaching importance to dreams, signs, opening the Bible at random, expecting the Lord to make it open so that they can gather his will from the first passage they see, 'impressions,' 'assurances,' etc. Practically, it gives great support to other delusions which claim a supernatural element. It greatly injures Christianity by subjecting it to a test which it cannot endure. It directs attention from the moral and spiritual transformation which Christianity professes to work, a transformation which, wherever made, manifests its divinity, so that none who behold it need any other proof that it is of God. It destroys the ascendency of reason in the soul, and thus, like similar delusions, it is self-perpetuating; and its natural, and, in some minds, its irresistible tendency, is to mental derangement.

"Little hope exists of freeing those already entangled, but it is highly important to prevent others from falling into so plausible and luxurious a snare, and to show that Christianity is not to be held responsible for aberrations of the imagination which belong exclusively to no party, creed, race, clime, or age."

A Noble Act.

One of the latest, if not the latest, of the applicants for the benefits of M. Pasteur's assistance is Mr. Harris, a student of Charing-Cross Hospital (London). Courage and self-devotion are virtues so frequently, we might indeed say so constantly, practiced by members of our profession, that they come to be looked upon as common-place and of every-day occurrence unless occasionally attention be drawn to them. Mr. Harris was taking luncheon at the restaurant of the Grand Hotel, when a dog which appeared affected with rabies attacked a lady there present. Mr. Harris seized the animal by the throat and got it safely out of the building, but in trying to twist his chain round him to render him incapable of inflicting injury, the young man, although the dog was muzzled, received a bite. He started on the next day with a friend to place himself under M. Pasteur's care, for the dog, being taken to the Battersea Home, died of rabies. We hope, whether

by M. Pasteur's inoculation or by the percental immunity of bitten persons, Mr. Harris will not suffer for his bold and generous intervention.

Women in Medicine.

The result of the late elections by competitive examination for resident physicians at Blockley must be very gratifying to the women doctors. Thirty-six young physicians applied for these appointments, five of them women and thirty-one men. Of the five women, two passed the examination, and of the thirty-one men fourteen were successful. More than that, the whole list of sixteen is led by a woman, Dr. Harriet W. Brooke, while her companion in the new Blockley staff, Dr. Helena J. Price, stands the eleventh in the full number. Drs. Brooke and Price were educated at the Woman's Medical College in this city, and the other applicants were graduates of various medical colleges of the first rank.

The American Medical Editors' Association.

This association held its annual meeting May 3, at the St. Louis Press Club. After an address by the President. H. O. Walker, M. D., of Detroit, the editors sat down to dinner as the guests of the Medical Press and Library Association. J. V. Shoemaker, M. D., of Philadeldhia, was elected President; Dudley Reynolds, M. D., of Louisville, Kentucky, Vice-President; and William Porter, M. D., of St. Louis, Secretary. This was the most successful, harmonious, and enjoyable meeting that the association has ever held, owing to the cordiality of the local medical press.

Expert Testimony.

Judge C. C. Fuller, of Mecosta county, in the case of "State of Michigan *vs.* Vanimmans," decided, when a physician refused to testify on the ground that the evidence would be expert testimony, "after many years' study and observasion, I decide that a physician's knowledge is his stock in trade, his capital, and we have no more right to take it without extra compensation than we have to take provisions from a grocery without pay to feed the jury. The court rules that the witness is not *compelled* to testify."

An American Dinner to M. Pasteur.

Mr. McLane, the American Minister, presided at a dinner which was given on April 14th to M. Pasteur. In proposing the health of the distinguished guest, Mr. McLane referred to him as a benefactor of humanity, to whom America was extremely grateful. M. Pasteur made an appropriate response, and closed by proposing a toast to the Union, and to the friendship existing between the United States and France. 120 French, English, and American guests were present.

Dr. Flint's Successor.

Dr. Edward G. Janeway has been appointed Professor of the Principles and Practice of Medicine in the Bellevue Hospital Medical College, in the place of the late Dr. Flint. In recognition of Dr. Flint's long and distinguished services at Bellevue Hospital, the Commissioners of Charities and Corrections have decided, at the request of the Medical Board, to put up in that institution a mural tablet to his memory.

Poisonous Candy.

Two brothers, candy dealers in New York, have each been fined $100 for selling "rock and rye" drops, which on analysis by Professor Edwin Waller, of the Health Board, were found to contain fusel oil.

Personal.

—Dr. C. C. Vanderbeck, of Philadelphia, has gone to California for the summer.

—Dr. Louis L. Seaman, late Chief of Staff Charity Hospital, and for several years head of the Maternity Hospital Service and Training School for Nurses, B. I., has arranged to receive at his private residence, 193 Second avenue, New York city, a limited number of ladies who may require such special attendance, especially such maternity cases as demand unusual vigilance, where miscarriages have become habitual, or where difficult or perilous labor or uræmia is apprehended.

—We have had very favorable reports from several parties who have used Nestlé's milk food. It is one of the standard preparations of the kind in the market, and has an excellent reputation both in Europe and America.

Items.

—The *Lancet* announces the death of Dr. Joseph Nowak, Professor of Hygiene in the University of Prague.

—Says the *Weekly Medical Review:* When is the laryngologist suggestive of the clergyman? When he says, Let us spray.

—The Columbus Medical College graduated a class of nineteen at its annual commencement on March 5th.

—Dr. E. G. Janeway has been appointed Professor of the Principles and Practice of Medicine in Bellevue Hospital Medical College, in succession to the late Dr. Austin Flint.

—Dr. Brown-Sequard has seen cases of intense pruritus caused by coffee drinking. The trouble was relieved when the coffee was given up, and returned when its use was continued.

—The Colleges of Physicians and Surgeons of Edinburgh and Glasgow have just decided to throw open to women their conjoint examinations and "triple qualification" in medicine, surgery, and midwifery.

—Pasteur has been prosecuted for practicing medicine and surgery without being legally qualified. The case, however, fell through, his defence being that he employed a duly qualified medical man to perform his operations.

—The fifty-second annual commencement exercises of the medical department of the Tulane University of Louisiana were held on March 31st. A class of 63 was graduated.

—A bill for an act to regulate the practice of medicine and surgery in the State of Iowa has recently passed the Legislature of that State and become a law, though its penalties are not to be enforced until January, 1887. The law is similar in many of its features to the well-known Illinois law for regulating the practice of medicine and surgery.

—A contemporary estimates that coca is used by 10,000,000 of the human race; betel nut by 100,000,000; chicory by 40,000,000; coffee by 100,000,000; 300,000,000 eat or smoke hashish; 400,000,000 use opium; 500,000,000 use tea; and all the known people of the earth are addicted to the use of tobacco.

—According to the *Kievlanen*, in Pereïslavl there lately died a Jew, named Sribnyi, aged 117, who up to his last remained hale and sound, possessed an acute memory and sane intellect, and even, a few months before his end, contemplated marrying a ninth time. His eldest son was only 82 years old, but looked much older.

—The Sultan of Turkey has decided to send a commission to M. Pasteur's laboratory to study his method of inoculation for hydrophobia. The members of the commission are Zocros Pasha and Hussein Bey, medical men, and Husni Pasha, veterinary surgeon. Zocros Pasha will present M. Pasteur with the Order of Medjidie and $2,000, a subscription from the Sultan for the Pasteur Institute.

—Dr. G. F. Harvey, of Parsons, Kansas, reports in the Kansas City *Medical Index* a case of a young woman who had suffered since childhood from cardiac asthma and emphysema. A few days before death, while suffering from general anasarca, she had a temperature under the tongue of 92° F.; two days later it was 94° F. She died three days subsequently.

—MM. Landouzy and Quérat, at a recent meeting of the Société Médical des Hopitaux, read a paper on Infantile Tuberculosis. They arrived at the following conclusions. Tuberculosis in infancy, from birth to the second year, is more frequent than is generally believed. It is generally localized, as a broncho-pneumonia; tuberculosis is transmitted to newly born infants either by contagion or heredity.

—M. Lessenne, at a meeting of the Société Médicale d'Amiens, indicated a certain sign of death, simple and trustworthy. After pricking the skin with a needle, the puncture remains open, just as when a piece of leather is pricked. On the living body, even if the blood does not come to the surface, as would happen if the person were hysterical, the pin-prick closes at once, and does not leave the slightest trace.

—At the annual meeting of the Tennessee State Medical Society, held at Memphis, on April 6 and 7, the following officers were elected for the ensuing year:

President—Dr. W. T. Briggs, of Nashville.

Vice-Presidents—Drs. J. W. Penn, of Humboldt, and J. B. W. Martin, of Nashville.

Secretary—Dr. Ambrose Morrison, of Nashville.

Treasurer—Dr. Richard Cheatham, of Nashville.

The Society adjourned to meet in Nashville on the second Tuesday in April, 1887.

QUERIES AND REPLIES.

Pruritus Ani.

Eds. Med. and Surg. Reporter:

In the Reporter of the 3d inst., Dr. W. C. E., of Minn., asks for treatment for pruritus ani, in "healthy subjects in the prime of life," as he describes them:

℞. Bichlor. hydrarg., gr. viij.
Aquam, Oj. M.

The above solution applied night and morning, with frequent ablutions, will give immediate relief. Try it.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

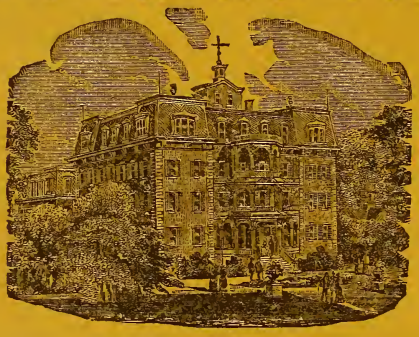
BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

15155605-

BURN-BRAE.



This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful Home.

TYPHO-MALARIAL FEVER: IS THERE SUCH A DISEASE?*

BY T. J. HAPPEL, M. D.,
Of Trenton, Tenn.

Is there such a specific disease as typho-malarial fever—a hybrid disease, produced by the joint action of two specific poisons, each one of which, acting alone, would produce a different and distinct disease?

I unhesitatingly answer in the negative. In medicine we are too prone to use terms to hide our ignorance, or to attempt to explain some phenomena of diseases that are unusual. Typhoid pneumonia, typhoid bronchitis, typhoid everything, are in many cases subterfuges and scape-goats, excuses for delays in curing cases or relieving patients that we are treating. In the same way, a case of remittent fever that is disposed to be obstinate, and does not respond to usual remedies, is designated typho-malarial. At the very outset of these remarks I wish not to be misunderstood. I do not deny the to-some-extent co-existence of malarial poison as a *complication* of typhoid fever (though this is denied by some of our best medical writers), nor do I deny the effect of the malarial poison, whether that poison be of an animal or vegetable parasitic nature or not, in producing departures from a *typical* case of typhoid fever. I would not deny this effect upon typhoid fever any more than I would the same as producing departures from *typical* cases of pneumonia, bronchitis, scarlatina, and most other diseases that occur in a section where malaria abounds. How few cases of pneumonia in our section of this State present a typical temperature chart, and how many of them show great variations between the morning and the evening ranges! How few cases of typhoid fever show a daily range of only $1\frac{1}{2}°$ to 2°. I trust then that my position is plainly stated: that malaria may complicate typhoid fever, as it may any other disease, but that the result is not a hybrid disease.

We all know that in different years, and frequently that at different seasons of the same year, the same disease will present different types; at one season being of a sthenic type, at another of an asthenic type. At one time, and with one type of a disease, we will use depressing, sedative remedies; at another, with the other type of disease, we will resort to the remedies of the opposite class. No physician who has been treating cases in which the marked tendency in *all* had been the asthenic type of disease, would bleed a patient with pneumonia or resort to any other depressing remedy. So too in cases of malarial fevers, we may have in them at times a tendency to a pernicious type of disease, and a disposition to continue and become, so to say, typhoid, from the very fact that the tendency to adynamia is not recognized, and the treatment resorted to either pushes the fever on in that direction, or at least does not check the innate tendency thereto.

No physician here present will venture to assert that at all times, and under all circumstances, a given amount of quinine will cure remittent or intermittent fevers. How often has he found the opposite state of facts to be true? Many of our malarial fevers

*Read before the Medical Society of the State of Tennessee, April 6, 1886.

are easily met by moderate doses of quinine, many by larger doses, and upon some quinine seems to have no effect. These continue, running a course of from three to six weeks, and then either apparently respond to quinine, or recover without, or in spite of it. These are the cases that too often many are disposed to call typho-malarial. In doing this, they base their diagnosis upon the fact that quinine, which is considered a specific against the organisms producing malarial fevers, has failed in this particular case. They forget that in some cases much larger doses are required to combat successfully the poison, and have been using enough to only excite the system and cause the germs to grow more vigorously.

Then, too, it cannot be denied that there are persons from whose systems quinine is eliminated so rapidly that it has no effect, under ordinary circumstances, upon the disease. It must, in treating such cases, be remembered that in three hours after the administration of quinine its presence can be detected in the urine of the patient, and that in proportion as the quantity excreted is large, so must the quantity administered be increased. In some few cases, when administered by the mouth or rectum, quinine purges, and of course does no good. In such cases the hypodermic administration of the remedy might be effective, when it would signally fail in any other way. Many physicians diagnose as typhoid fever any continued fever that refuses to respond to the use of quinine in full doses, without regard to the distinctive abdominal symptoms of that fever, or to any of the foregoing facts.

All present, doubtless, know the orgin of the term typho-malarial.

Dr. Daniel Drake, about fifty years ago, recognized the fact that typhoid fever received certain impressions from existing malarial poisons. Observant clinicians have noticed this fact in all parts of the malaria-producing zone, though generally it has been greatly exaggerated. The word, or term, typho-malarial, was coined by Surgeon J. J. Woodward, to express his conception of a composite fever. The war gave rise to many expressions, but to none furnishing a nicer subterfuge to physicians than typho-malarial. The name itself is sufficient in many families to account for the duration of an attack of continued remittent fever. To tell a patient that he has remittent fever is to lead him to expect to recover in a short time, a week or two at most; but call it "typho-malarial," and if he escapes with his life he is thankful This an age of high-sounding technicalities. and a physician ought to be excused for attempting to coin a new name for an old disease.

Surgeon Woodward, when treating those cases of fever which occurred amidst the swamps of the Chickahominy, and that, too, among men who, in many instances, had never before been exposed to malarial influences, might reasonably have thought that he had discovered a new fever. Soldiers exposed for the first time to miasmatic or malarial poisons, furnished the best nidus that could have been selected for the growth of the disease germs. Thousands of the army were attacked. Dr. Woodward reports 57,400 cases of typho-malarial fever, with 5,360 deaths, it being a death-rate of a little more than nine per cent. In the same statistics he reports 79,462 cases of pure, uncomplicated typhoid fever, with 30,336 deaths, the death-rate being a little more than 38 per cent. Note the contrast in the two death-rates, the former being not quite one-fourth the latter. Had the first set of cases been what is usually claimed as a combination or joint action of the two poisons, producing a specific disease, known as typho-malarial fever—a fever in which we have a remittent form or type of fever followed by a typhoid fever, modified, and then this by an intermittent or remittent fever, the death-rates certainly ought to have been reversed, unless as Dr. Bemiss holds "the presence of malaria in the blood does not exercise an unhappy influence upon disease due to the specific poison of typhoid fever." A further begging of the question upon this point of death-rate of the two diseases asserts, "It may, on the contrary, be ascertained that it (malaria) modifies the typhoid process, so as to deprive it of some of its most dangerous features." This statement is made in the face of a well-known and generally recognized fact, which he had stated in the same paragraph as follows: "When an acute inflammation is complicated with malaria, its prognosis is more grave." He might have gone one step further with another truth, which we in West Tennessee recognize, "that the prognosis in *any* acute disease is rendered more grave when complicated by malaria." Prof. Flint, in his excellent work on the Practice of Medicine, in referring to the death-rate in the so-called typho-malarial fever, says: "The duration of the febrile career is apt to be longer and the gravity of the disease is greater."

These troops were surrounded by everything favorable to the development of grave types of intermittent and remittent fevers,

which diseases would not respond to the usual doses of quinine and the routine treatment nearly always resorted to in hospital practice. These cases lasted from two to five weeks, and an excuse for so doing must be found, hence the coinage of the term typho-malarial as applied to fevers.

Later on, Dr. Woodward in 1876 retracted his statement made, in which he had claimed this as a specifie fever, and at the International Medical Congress held in Philadelphia in that year, offered the following resolution, which was adopted: "Typho-malarial fever is not a specific or distinct type of disease, but the term may be conveniently applied to the compound forms of fever which result from the combined influence of the causes of malarial fevers and of typhoid fever." Whilst the term might be *conveniently* applied, we would have the same right to hybridize some name to apply to bronchitis, which so frequently occurs in the course of typhoid fever. The one is no more a complication than the other.

Dr. Bartholow always opposed Surgeon Woodward's ideas in reference to typho-malarial fever, asserting as follows: "Typho-malarial fever has then no reason to be admitted as a morbid entity into nosological systems—does not in fact exist. All that can be claimed for it is, that when typhoid fever occurs in an individual saturated with malaria, the fever is modified somewhat in its course—has more of the remittent type, and is apt to be more protracted, owing to the occurrence of intermittents during convalescence." He too, then, would clearly hold that the death-rate shown by Dr. Woodward in his cases occurring among the soldiers in the Chickahominy swamps proved conclusively that they were only severe cases of remittent fever.

As late, however, as 1884, Dr. Bartholow, in referring to the so-called typho-malarial fevers, is more pronounced in his views against the existence of any such hybrid disease. He says: "I much doubt the existence of a typhoid fever whose symptoms are modified by a malarial fever. Indeed, there are reasons for believing that in a certain sense an antagonism exists between the two, so far that in the presence of the typhoid poison the malarial ceases to be active. I have always held that the thermal line of typhoid fever might receive an impression from a co-existing malarial complication, might, therefore, become more distinctly remittent, but further experience has weakened this belief. If the morbid anatomy of typhoid fever is not thus affected, why the symptomatology? Examined anew in the light of a wider experience, I have been conducted to the conclusion that the modification in the thermal line supposed to be due to a malarial complication, has, for the most part, no real existence." (*Medical News*, September 13, 1884.) It is impossible to make a diagnosis of such a disease as typho-malarial fever. It is either typhoid fever or it is malarial. In malarial fevers we have none of the peculiar abdominal symptoms of typhoid fever, and when these abdominal symptoms exist, viz: "meteorism, tenderness on pressure, especially in the right iliac region, and gurgling, especially the two former, conjoined with diarrhœa, or a tendency to hypercatharsis, with ochre-colored discharges, typhoid fever is present." There may be a decided diurnal range of temperature, but still it is a case of typhoid fever, and will run a definite course unchecked by quinine, the controller of malarial fevers. It is true that the administration of quinine in typhoid fever will stop the excessive diurnal variations in temperature, but it will do the same in all other diseases, by virtue of its antipyretic effect.

No authority examined by me has made any effort to differentiate the disease by post-mortem examinations. The lesions shown in cases which had been diagnosed as typho-malarial, were either those of *typhoid* fever *alone*, or of *malarial* fever *alone*. There were found either the diseased Peyerian patches, and solitary glands, or the enlarged and softened spleen and liver, together with the characteristic bronzing of the latter organ. A distinct disease ought to present features, either during life or after death, by which it could be positively diagnosed; and one in which this cannot be done, has no claim to a separate entity. Hartshorne, in Reynolds's System of Medicine, referring to the so-called typho-malarial fever, quoting Surgeon Woodward's idea, represents the fever as one due to three distinct poisons, viz., that of malarial fever, the specific typhoid poison, and the poison of scorbutus, and that whatsoever one of these elements or poisons is in excess, it controls the type of the disease, making present either malarial, typhoid, or scorbutic symptoms. As said already, I do not attempt to deny in toto the existence of these complications, or their effect as such upon typhoid fever, when present, but they are simply complications. In reference to the morbid anatomy in these cases, it is said by the writer above referred to, that the most important was the intestinal lesion "*similar* to that of typhoid fever, but not identical."

He adds further, whilst claiming the presence of malaria, "We have the local lesion of the glands of Peyer, and the mucous membrane of the bowels, recalling enteric or typhoid fever," thus admitting exactly what we have claimed, namely, the existence of typhoid fever.

Dr. Bemiss, an advocate and supporter of the typho-malarial idea, is cautious in making a diagnosis of the existence of typho-malarial fever, unless the nervous symptoms are well marked, together with the bowel symptoms, and rose spots. He determines the presence of malaria by the previous history and symptoms early in the attack, chief among which is the decided rise of fever in the onset of the disease, but admits that if the morbid processes of typhoid fever are violent, there may be stages where it is impossible to detect the presence of malaria *per se* in the case. He holds, however, that the *typhoid* CONDITION in malarial fevers can generally be differentiated without trouble. In other words, we cannot have typho-malarial fever without a case of true typhoid fever, and that the malarial complications show themselves early in the disease by irregularities in the daily range of temperature. This is another case of "petitio principio," for any one who has practiced in a section abounding in malaria will admit that all diseases are more or less altered in type by its presence. Surgeon Woodward in describing his typho-malarial cases writes as follows: "Of the form in which the malarial element prevailed, the somewhat abrupt commencement, gastric disturbance, icteroid skin and tongue, with remissions tolerably distinct, were predominant features. The lenticular spots of typhoid fever and the sudamina were often wanting." A more striking picture of pure, uncomplicated, severe, not to say pernicious, cases of remittent fever could scarcely be drawn. Evidently the reason for such cases being called typho-malarial was because they did not readily respond to quinine. The abdominal symptoms in those cases of so-called typho-malarial fever were those of malarial fever alone, and this fact ought to have aided much in making a diagnosis in cases otherwise obscure. In most cases constipation existed, though in a few there was diarrhœa, but in all the discharges were dark, tarry, or green, not ochre-colored, as in typhoid fever.

Dr. Bribach, in the *St. Louis Courier* of August, 1885, attempts to diagnose typho-malarial fever from typhoid fever by asserting that in typhoid fever the prodromal symptoms would probably be more prolonged, whilst we know that the prodromic period is a very uncertain time, varying, according to Prof. Flint, from one to ten days. That the temperature of typhoid fever does not attain its maximum on the first day; but we know that when typhoid fever is ushered in by a well-marked chill, as it sometimes is, it would be reasonable to expect a maximum temperature at the outset. That the abdominal symptoms are wanting in the great majority of typho-malarial cases, but these are the very ones which we contend are remittent fever cases. That in those which are complicated by diarrhœa, gurgling, and tenderness over the cæcum, the diagnosis is for the time difficult or impossible. He differentiates the disease from the *remittent* fever by the quinine test alone. He says: "If quinine in full doses *i. e.*, two twenty-grain doses in the first day, and twenty grains in a single dose on the second and third days, produces a state of complete apyrexia on the third and fourth days the disease is not typho-malarial fever." He forgets a fact stated in the first of this article, that some persons are not specifically affected by quinine, and upon them it seems to have no effect; and again, as a test, it would be far surer to use smaller doses (grs. iv.), repeated every two hours, than to attempt to make a diagnosis on a single large one. In his history of typho-malarial fever he says that bronchial catarrh was so frequently present that it could hardly be called a complication. In this same article, the writer holds that typho-malarial fever "is clearly a misnomer; that the disease presents a distinct type of continued malarial fever mostly resembling a variety described by Dr. Maury under the head of 'malarial continued fever.'" From a careful study of his description of the cases treated by him, I am satisfied that the disease was an obstinate remittent fever, with an occasional mild case of typhoid fever, and his acceptance of the term "malarial continued fever," is a virtual concession of everything we have claimed in this article.

The death-rate in Dr. Bribach's cases of so-called typho-malarial fever was only one in twenty—even less than in those of Dr. Woodward; whilst Prof. Flint holds, and common sense teaches, as already stated, that the mortality ought to be greater in typho-malarial than in typhoid fever.

In the paper read by Dr. Evans, of Shelbyville, before the 1885 meeting of this Society, the fever described by him is the one we always have in this section of the State, when typhoid fever in a severe form appears. He uses the following language in his article on typho-malarial fever: "Again, whilst we

rarely see the characteristic pathological symptoms of typhoid fever, the ataxic symptoms are well marked: such as low delirium, subsultus tendinum, diarrhœa, with tympanites, iliac tenderness, and sometimes hemorrhage of the bowels, which adds greatly to the gravity of the disease." This, in my experience, is the typhoid fever of West Tennessee. In patients surrounded by, and under, malarial influences, their systems are more or less saturated with this peculiar poison, and hence we have frequent departures from typical cases of typhoid fever, as described by Louis, but nevertheless the disease is typhoid fever. The intercurrent complications do not change the character of the typical lesions. There are many circumstances that favor this non-conformity to type in typhoid fever, and I assert boldly that almost every physician, who has treated a score of cases of this fever, has met with not more than two cases presenting exactly similar symptoms. And again, I assert that we treat cases of what we are disposed to call "continued fever," presenting not more than one or two symptoms of typhoid fever, and shortly after, or during the convalescence of the first case, a second one occurs in the same family, and then a third, a fourth, and probably others—none of them typical cases of typhoid fever, but when grouped together, a clear and unmistakable diagnosis of typhoid fever is made. These are sometimes the cases diagnosed typho-malarial, but oftener obstinate cases of remittent fever are so called.

In my own practice I have met with cases of remittent fever that have continued from two to four weeks in spite of quinine, and which I would have been glad to have diagnosed as typhoid fever, or better still, as typho-malarial.

I have recorded one case, which occured August 3d, 1873, as my first experience with obstinate remittent fever. This patient presented the usual symptoms of an ordinary attack of remittent fever, but no effect could be produced upon it by quinine (ergo, a case of typho-malarial fever, as would be claimed by those who support the typho-malarial theory). Quinine was given in large doses, and in small doses, per orem, with no effect, so far as terminating the fever was concerned. After using many remedies for more than two weeks, the case recovered rapidly under ten-drop doses of fl. ex. gelsemium, carried to the extent of producing ptosis and double vision.

In another case, which I treated in August, 1883, the patient presented many of the symptoms of typhoid fever, except hypercatharsis, and tympanitis, and would not respond to quinine, per orem or per rectum.

On the fifteenth day of the disease, I began the use of fl. ex, eucalyptus ʒ j every four hours, with a decided amelioration of all the symptoms in twenty-four hours, and a complete abatement of the fever on the twenty-first day, and a rapid convalescence. These two cases are examples of that class of cases that practitioners of medicine are too ready to denominate typho-malarial.

No doubt many so-called cases of typho-malarial fever would respond readily, as did those two, to the use of some other antiperiodic. Quinine will not cure all cases of malarial fevers. Nearly all medical writers recognize this fact.

In those obstinate cases, it becomes necessary to produce a decided impression upon the nervous system, and whilst gelsemium may act promptly in one case, and eucalyptus in another, strychnia may be better in a third, arsenic in a fourth, and so on.

Some practitioners show excellent results in those cases of continued remittent fevers from the use of tartar emetic.

Many are disposed to diagnose a case as typho-malarial, when all of the other symptoms of typhoid fever co-exist with constipation, regarding constipation as contradicting the existence of typhoid fever, in face of the evidence of such authorities as Flint, Murchison, Hutchinson, and many others to the contrary. The last case of typhoid fever which I treated showed no tendency to diarrhœa; in fact, the bowels acted from enemata only, used once or twice per week. I might refer to other points of minor importance connected with the subject, but I desist.

CIRCUMSCRIBED PERITONEAL DROPSY SIMULATING OVARIAN DROPSY.*

BY H. P. C. WILSON, M. D.,

Of Baltimore, Md.,

Surgeon to the Hospital for the Women of Maryland. Fellow of the American Gynæcological Society, and British Gynæcological Society. Member of the British Medical Association. Vice-President of the Baltimore Gynæcological and Obstetrical Society, etc., etc.

Mr. President and Gentlemen of the Academy of Medicine: I desire to call your attention this evening to a case of circumscribed abdominal dropsy, limited by peritoneal adhesions so complete as to accurately simulate ovarian dropsy. It could not be called cystic dropsy, because the fluid was not contained in a distinct sac; but by adhesions from gen-

* Read before the Academy of Medicine, March 2, 1886.

eral peritonitis, the fluid was restricted to the front and lower part of the abdomen, and not allowed to gravitate throughout its whole extent. Change of the patient's position did not change the position of the fluid, and there was nothing in her history or symptoms to cause us to suspect a former, or recent, peritonitis. She had never been sick a day in her life, and all her organs were acting well.

Mrs. Jas. P., married, æt. 38. The mother of seven children—twins once, four miscarriages—four times delivered with forceps. Began to menstruate at 14. Noticed a swelling in the abdomen 1st of September, 1885. Could not locate its beginning in either groin or lower abdomen. Has had regular menstruations always, except when pregnant.

She was sent to me by Dr. N. B. Baker, one of the most eminent physicians in Martinsburg, with the statement that she had an ovarian tumor. I confirmed his diagnosis, when she was admitted to the Union Protestant Infirmary, February 12, 1886.

She had a prominent fluctuating tumor of the lower abdomen. Dull on percussion to two inches above the umbilicus, dull in either groin, and presenting the characteristic roundness and prominence of a cystic tumor of the ovary. Percussion was clear in both lumbar regions. Changing the patient's position did not change the lines of dulness anywhere. There was no tenderness over the abomen to any amount of thumping or pressure.

The uterus was free in the pelvic cavity, and measured three inches by the sound. She had the facies ovariana. I had no doubt that the case before me was one of cystic disease of the ovary.

February 15, at 2 p. m., was appointed for the operation; sponges, instruments, rubber cloths, and dressings, had been thoroughly carbolized. The carbolic spray had been going on in the operating room for one and a half hours, but was stopped before the operation began. Dr. N. B. Baker (whose patient she was) and Drs. Keyser, Fawcett, and Robert T. Wilson were present, with the two hospital nurses. The patient was given ʒj of whisky, and chloroformed by Dr. Keyser. I again reviewed my former examination, and was satisfied that I had a simple cyst of the ovary, without complications, to deal with.

Not feeling well, nor in an operating humor, I handed the instruments to my son, Dr. Robert T. Wilson, and told him to proceed with the operation. He cut carefully into the abdominal cavity, making an incision of three inches, down to the peritoneum, and entering the cavity by an opening of about half an inch. Immediately, there was a gush of a greenish-yellow fluid, and turning the patient on her side, about one and a half gallons escaped; enlarging this opening to three inches and looking in, a solid tumor was discovered about nine inches long, six inches broad, and three inches thick. The walls of the abdominal cavity were festooned with recent lymph, and patches of the same were seen everywhere. The hand passed in, found adhesions everywhere. The uterus and ovaries were normal, but we could not determine by the touch and sight what this tumor was, till we had lifted it from the abdominal cavity, and found it was made up of coils of intestine agglutinated with lymph. It was so firm and solid, that at first sight it was hard to believe it a mass of intestines. It was not agglutinated to other abdominal viscera, but seemed to be free in the peritoneal fluid.

Dr. Robert Wilson returned the mass to the abdominal cavity, and closed the abdominal opening with seven silver wires, and dressed the wound as usual in ovariotomy.

Thus the case which I was sure was ovarian dropsy turned out to be localized peritoneal dropsy, the result of peritonitis.

This woman told me before the operation, and has several times confirmed her statement since, that she had never been sick a day in her life, except during confinements, and her youngest child is now two years old. Dr. Baker, who has been her physician ever since her marriage, assured me that her statement was correct.

For my diagnosis I had before me a fluctuating tumor, occupying the lower part of the abdominal cavity, and the abdomen was rounded prominently about the umbilicus. In the dorsal position, it did not bulge out to either side. There was clearness on percussion in both lumbar regions. Changing the position of the patient did not change the lines of dullness on percussion. She had no tenderness on abdominal pressure. All of her organs were acting well, and the pelvic viscera were as they should be in such a supposed ovarian cyst. No anasarca; no œdema of lower extremities.

I do not see how we were to avoid falling into the error into which we were led. Had we tapped her (which should never be done in ovarian tumors, if possible) we would have been none the wiser, but would rather have had our diagnosis confirmed by the solid tumor which would have remained. I have not implicit confidence in the ovarian cell as a means of diagnosis.

Dr. Peaslee says in his book on ovarian tnmors, "It might be expected that the removal of all the fluid from the peritoneal cavity would at once decide between ascites and an ovarian cyst. But Dr. McDowell and Dr. A. G. Smith had a patient who had tapped herself with a trocar and canula 90 times, in whom, on opening the abdominal cavity to remove an ovarian cyst, they found only a mass of intestines matted together by adhesions."

Dr. T. Spencer Wells in his work on ovarian and uterine tumors says: "The fluid poured out as the result of inflammation of the peritoneum, instead of lying free in the cavity, is sometimes confined in pouches formed by adhesions among the viscera, or by false membrane deposited during the disease, or by attachments of the omentum or mesentery." "The fluctuation, even if distinct, is always limited in extent and confined to the same spots. The intestines are found behind or beside the tumor, and do not as in ascites rise up to the front of the abdomen, or vary with the position of the patient."

(*To be continued*).

ALBUMINURIA.

BY JOSEPH T. SMITH, M. D.,
Of Baltimore, Md.,
Visiting Physician to Bay View Hospital.

(*Concluded from page* 678.)

If, however, the amount is small, but a trace indeed, there may be a condition such as Roberts terms physiological albuminuria; this is a condition of things difficult to recognize; we must find the amount of albumen small; it must not be constantly present, that is, it must be intermittent, absent, for instance, in the urine passed in the morning, but showing itself during the day after food and exercise, as Brown-Sequard has shown its presence after a full meal of eggs; finally the albumen must be long continued. Supposing it to be a normal product, we know, as yet, no way of determining the fact from the discovery of albumen alone, how much shall be looked upon as normal, and when the normal becomes abnormal. We can only determine by a careful inspection of the whole body, and if we find no diseased condition we say the albumen is a normal product; the simple presence of albumen tells us nothing, it awakens suspicion only. Again there seems to be no doubt that many cases looked upon as physiological, if carefully looked into, will be found to depend upon some systemic fault, not it may be in the kidneys, but elsewhere, as in those broken in health or who suffer from dyspepsia. Dr. Mahomed states that "he found albumen in the urine in 9 out of 58 persons (namely 15.5 per cent.) thought to be healthy, whom he examined for life insurances. It was shown that 7 out of the 9 cases were not in perfect health. At best then physiological albuminuria is exceedingly rare, and a case should not be pronounced such until the fullest examination of the whole body is made. So far as we know now, even a trace of albumen should cause apprehension, and we should not rest until we have exhausted all sources of information as to cause. Dr. Greenfield remarks in this connection, and we heartily agree with him: "There are cases—I have had such under my care—in which there was no evidence of disease beyond the presence of albumen in the urine, and in these cases not merely intermittently, but in one or two cases continuously, during a period of some months, though in variable quantity. In the cases to which I refer there was neither dropsy nor cardio-vascular changes, and none of the serious disturbances which we find in Bright's disease; these subjects were especially anæmic young women.

The urine was usually pale, clear, of low sp. gr., often phosphatic, and contained neither casts nor blood. But are we on this account to say there is no disease, that it is a physiological albuminuria? I believe that, as pathologists, we are bound to allow of no such conclusion without the most exhaustive analysis and conclusive evidence.

If we look at the list of diseased conditions in which albumen may be found in the urine, we will find them almost legion; so many and so diverse are they indeed, that one learns but little as to their nature from the fact that albuminuria is present. This is a symptom of so little moment in many conditions that we do not even look for it. Such is true of rheumatism, ague, measles, etc.; in others, on the contrary, it is eagerly sought for that we may know the tendency of the diseased conditions present, as after scarlet fever and certain forms of Bright's disease; still even here it has but a secondary place, for without the microscope and a thorough examination of the patient, we can learn but little of the actual conditions present. Still further, even in some forms of fatal disease, as after scarlet fever, no albumen may be found, showing that thus, even when you would look most for it, it may disappoint you by its absence. Upon this point Dr. Greenfield well remarks: "It is a well known fact

that extensive disease may exist in the kidneys, remaining for a long time entirely latent, and reveal itself by some terminal fatal phenomena, or be discovered after death. I have for some years made it a special object to examine all kidneys, whether obviously diseased or not, whenever opportunity permitted, more especially in cases of men dying over the age of 30, or dying from acute diseases of all kinds, and have been struck with the frequency with which changes of an extensive character have been found where none were suspected during life."

One needs but glance at the various bodily disorders in which albuminuria exists to see with what comparative ease the urine can be made albuminous; not even a diseased condition need be present—simply throw too much albumen into the blood and in an altered form you will find it in the urine. The pathology of albuminuria is still a somewhat vexed question; the old idea that albumen is thrown out from the blood to be reabsorbed by the cells of the tubuli and so kept from showing itself in the urine having been disproved, has been replaced by that of Heidenhain, who taught that the albumen is kept back by the cells covering the outside of the glomerular tuft; so long as these are in good condition, the arterial tension not too great, and the blood not surcharged with albumen, these tests will fail to show an albuminous urine. Any condition of the cells of the glomerular tuft that will interfere with their function then may cause albuminuria, and as these may be true secreting cells, like those of the salivary and sweat glands, it is not difficult to explain how it is that so many diverse conditions have this one symptom in common.

As with all secreting cells, those of the glomerular tuft are very sensitive to any change in the blood supply to the tuft; thus heart troubles, fevers, inflammation, and that large class of diseases which cause increased arterial tension, will cause these cells to allow the passage of albumen; in the latter case it may be as some one has suggested by a partial tearing of the cement substance that binds these cells together, and thus the albumen escapes.

The cells of the glomerular tuft, if their function is now correctly known, are influenced by the slightest changes, oftentimes, in their blood supply, and the slightest disturbances of the normal circulation will cause albuminuria.

Dr. Mahomed, indeed, looks upon the increase or diminution of the circulation of the blood in the tufts as the two conditions most likely to produce albuminuria; indeed, they are the chief causes.

Thus the kidneys, like other organs, become congested; this may go no further, or may end in inflammation, and the cells covering the glomerular tuft show circulatory interference by allowing the albumen to pass out; in the one case it soon disappears, in the other it is increased in amount, and frequently the cells become more and more unfit to perform their function, and the first stage of Bright's disease, according to Frerichs, is fairly established.

We had intended to note other points in this interesting part of the subject, the difference in function of the cells of the glomerular tuft and those lining the tubuli, the mode in which the blood-currents influence the presence of albumen in the urine, how it is that the first signs of destructive disease commence in the glomeruli and tubuli, and thus cause albumen to be one of the first symptoms; but our time is already, we fear, more than exhausted.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Thursday, March 4, 1886.

The President, B. F. Baer, M. D., in the chair.

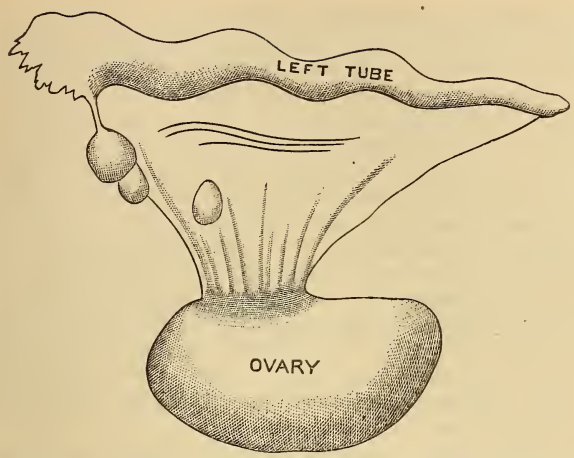
Menstrual Epilepsy.

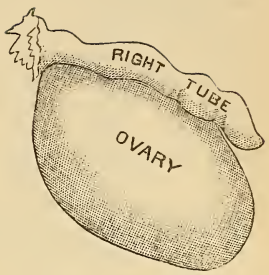
Dr. Howard A. Kelly exhibited recent specimens of tubal and ovarian disease removed within the past two weeks. The first specimens to which he called attention were removed from a patient twenty-one years of age, who has suffered from an aggravated menstrual epilepsy from the very first appearance of the function. There was no difficulty whatever in the removal through a small incision into which two fingers could just be slipped. The whole operation from beginning to complete closure took but twenty-four minutes. The right ovary was deformed by a very prominent nodule, about one and a half centimetres in diameter, which burst on removal, discharging a watery fluid, and was shown by its lining membrane to be the last corpus luteum.

The second specimens are rare examples of

Hydrosalpynx with Congenital Deficiency of Tubes and Broad Ligaments.

In this case there was malformation of the distal ends of the tubes, broad ligaments, and ovaries. The left tube is as large as a





bologna sausage. It was brought into view with great difficulty, after separating many light adhesions to the pelvic walls; while the isthmus is much enlarged and thickened, the great distention is at the involuted ampulla. The operator was materially assisted in bringing this tube into view by upward pressure on the cervix by a hand in the vagina. The fimbriated extremities were lost in a mass of vascular and fibrous tissue forming a broad ligament, and deep down in this were imbedded the somewhat hard elongated large ovaries. It was utterly out of the question to attempt a removal of the ovaries, and any such operation would have been of a very desperate character; nor did he, Dr. Kelly, regret this in the least, as he had planned his operation for *tubal* disease, to which he attributed all the patient's sufferings. The right tube was as large as his middle finger, and was also distended with watery fluid.

The other specimen is a very large

Hematosalpinx.

This tube, the left, about four inches long, burst as he was removing it, discharging four ounces of tarry blood. It was very adherent, having several attachments to intestine and omentum. The dilatation is here too seen to be at the ampulla, which extended far beyond the ovary, back into the cul-de-sac. The ovary is embraced by the isthmus, and presents a curious appearance as it lies, about twice the normal size, imbedded in a sort of a ball-and-socket manner below the isthmus. Where it is laid open, the tube is converted into one large sac.

Dr. W. Goodell had been surprised at the size of the tubes.

Dr. Jos. Price remarked that the tube was so large that the uterus had been pushed aside by it. Great care was required in its removal.

Dr. Chas. Hermon Thomas said that some time since he should not have recognized such a condition, but now he can; the result of experience in bimanual examination. He would like to hear further on this point of diagnosis.

Dr. B. F. Baer thinks it very unfortunate that the ovaries as well as the tubes could not have been removed in the case just reported by Dr. Kelly, for their presence will probably result in the usual monthly congestion, and consequently the pain and other pelvic distress, for the relief of which the operation was performed, may continue to exist. There are several cases on record in which the tubes were removed and the ovaries allowed to remain, but the results have not been reported. He can see no reason why this should be done, unless the ovaries can not be found, or some other insurmountable difficulty presents itself. He fully believes in the advantages of prolonged and thorough palliative treatment in these cases. Benefit usually follows, and sometimes cure; at least operation is rendered less difficult and more likely to be followed by recovery of the patient, both from the operation itself and the symptoms. Certainly the application of remedies such as iodine to the fundus of the vagina and the interior of the uterus, with prolonged rest and general building-up of the system, will have a strong influence in attenuating adhesions, promoting absorption of lymph, and possibly, if not probably, in cure of the patient without operation.

It should not be forgotten that removal of the tubes and ovaries in these cases does not cure absolutely in every case. He believes that we will be called upon in a few years by many of these cases which have been

operated upon, to relieve symptoms which still exist or have returned, and for the relief of which operation had been performed; just as we have been called upon from time to time and pestered by those old cases of chronic hypertrophy and retroflexion of the uterus with pelvic adhesions. He has now under his care one of his own cases upon which he operated for the relief of symptoms, the result of disease of the tubes and ovaries with pelvic adhesions. The patient made a good recovery, and appeared to have been cured, but the symptoms have returned, and she is now complaining almost as much as before the operation. She also has periodical attacks of metrorrhagia. This of course is an unusual case. He has another patient under his care, who was operated upon in a neighboring city by removal of the tubes and ovaries, and is treating her for the same symptoms of which she had complained before the operation. He is an advocate of the operation in some cases, but he pleads for due deliberation and the exhaustion of careful palliative and preparatory measures before operation is resorted to. Many cases will get well without operation. Some will not be benefited before operation is performed, and there is some danger in laparotomy, although Tait has had such remarkable success.

Dr. Da Costa inquired if Dr. Kelly had tried the benefits of rest and treatment before operating.

Dr. Joseph Price said that the recurrence of symptoms seemed to indicate partial removal of the tubes and ovaries. One of the fundamental rules of surgery is to seek for pus where it is probably present, and in all cases to remove it if possible. When the ligatures will cut through the tubal stump on account of its cheesy character, hemorrhage may be prevented by the application of the cautery.

Dr. Kelly, in closing the discussion, said he did not in the least regret that the ovaries could not be removed, as he had operated for tubal disease, not for ovarian; and he admired the zeal of Schroeder, who instead of always removing the ovary, sometimes resected diseased portions. In all the cases of tubal and ovarian disease upon which he had operated, months and years of careful treatment had been wasted; and now where he diagnosticated pyosalpinx, the only delay he allowed was to put the patient in the best possible condition for operation. Topical, external, and internal treatment is utterly futile, and never does more than secure temporary palliation.

Dr. Kelly's reliance regarding diagnosis lay entirely in a skilled bimanual examination, by which he always accurately mapped out all the peculiarities of the case before operation. If there is rigidity and resistance it is necessary to etherize, but he has yet to see the case where the presumptive signs were those of tubal and lesser ovarian disease where the structures could not be picked up between the two hands and outlined. He considers that this tact has been largely developed by persistently examining the condition of the appendages to the utmost possible extent as a routine practice, in all cases which come under his notice. Introducing the finger as high as possible by forcing the hand well under the pubic arch, and carrying the sensitive pulp up against the post-fornix or either lateral fornix, and then playing up and down with the other hand pressing on the abdomen and creeping a quarter inch at a time without ever fully relaxing, and letting structures in between roll through the two fingers, and in case of an ovary, running round its whole periphery, or of a tube, tracing it up to the cornu-uteri and down into the retro-uterine pouch, where it generally terminates, give often most surprising results, and would doubtless, if universally carried out, change hundreds of diagnoses of leucorrhœa, endometritis, and flexions with adhesions to the far more serious ones of pyo- or hemato-salpinx.

Pyosalpinx.

Dr. Joseph Price exhibited specimens of pyosalpinx from two patients, and afterwards remarked that Tait and Keith have ended the dark period by showing us how to operate on the abdomen and pelvis without fear and with little risk. The wonderful advance in pelvic and abdominal surgery should be placed to their credit. He believes it is now universally admitted that they have reached the very acme of perfection. One surely must be a convert to Tait's law to contend with the great difficulties in pelvic surgery—"That in every case of disease in the abdomen or pelvis, in which the health is destroyed or life threatened, and in which the condition is not evidently due to malignant disease, an exploration of the cavity should be made." Standard works on ovariotomy dwell at great length on the subject of adhesions as the most important and difficult complication with which the operator has to contend. In short, in pelvic operations the risk and the difficulty will ever lie in the separation of organized inflammatory products. Adhesions, when old, between the pelvic viscera

and diseased tubes, become degenerate, and hence easily ruptured. In one case only have strong adhesions, deep in the pelvis, stayed my hand. The right tube and ovary adhered strongly to the sac and right side of the uterus, and the whole adherent mass was absolutely inseparable. Again, the rupture of pus tubes or cysts filled with inflammatory, septic, or malignant elements, will be followed by serious symptoms. Operation becomes difficult when the ovaries and tubes, tightly distended with pus, and softened through pathological changes, cheesy in consistence, are matted together with the rectum and small intestines.

Uterine Applicator and Dressing-Forceps Combined,

exhibited by Dr. Charles Hermon Thomas.

This instrument, which is especially adapted to making applications within the cavities of the neck and body of the uterus, but which is also available for making dressings and applications to the vagina and external surface of the cervix, has borne the test of two years' use. It is in forceps form, the blades are strong and resistent from the handles forward about two-thirds of their length, when they narrow rapidly, so that taken together they become about equal in size to the ordinary uterine sound. This narrow portion, somewhat suggestive of the long beak of the angular ear-forceps, is about three and a half inches in length, the tips being roughened on their opposed surfaces. It holds securely the smallest pledget of cotton, and by reason of the springy character of the beak, will permit the locking of the handles when a full-sized pledget or tampon is placed within its grasp. The point is slightly probed, as an extra precaution when introduced to the uterine fundus, though a small cotton ball answers all needed purposes as a protective tip. I have usually employed the plain point on account of its occupying less space at the internal os uteri. The beak is curved to a shape corresponding very closely to that of Ellinger's dilator, which has been found so generally well adapted to entering the uterus. This portion is electro-plated with gold when so ordered (a proceeding of moderate cost and to be commended), as a protective against the corrosive action of iodine, iodized phenol, and the like, which so rapidly destroy nickel-plating and corrode polished steel surfaces. This instrument was made under my directions by J. H. Gemrig & Son, of this city.

Some practical points of use may be mentioned. Soiled or medicated cotton is easily removed with the use of one hand only, by

simply unlocking the handles and wiping the point in a crumpled paper, thus leaving the other hand free for other employment, and avoiding the trouble, the soiling of the fingers, and the whittling often involved when the wire applicator is used. In its use there is immunity from the rasp action of the closely wrapped cotton of the wire applicator, and also a greatly increased carrying capacity of the cotton for medicated liquids. Moreover, it will be found convenient and desirable to make use of the instrument as a uterine sound incidentally in certain instances. In my own experience it has proved practicable as an applicator, one fully meeting the needs of most cases, while as a uterine dressing-forceps for general use, it has been found so satisfactory as to have superseded all other instruments of this class.

Dr. Baer said the instrument presented by Dr. Thomas is a very ingenious one, and will doubtless serve a good purpose where the cervical canal is patulous. A greater quantity of the medicating agent used can be carried to the diseased surface than when the tightly wrapped cotton is used.

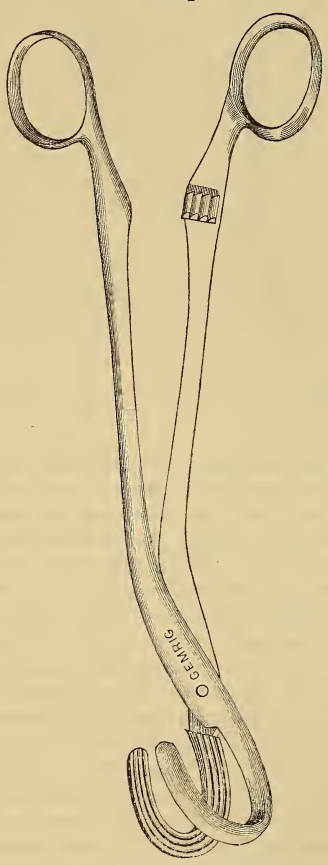
Dr. J. F. Wilson has nothing to add to what Dr. Thomas has said. He has used one for several months, and can agree with Dr. Thomas as to the ease of application and removal of soiled cotton.

Dr. Parish said that the forceps was valuable, and would be much used. As an applicator it will be very convenient. A few years ago the sound and applicator were too much used, but extremes either way are wrong. Applications to the endometrium are sometimes needed.

Dr. H. A. Kelly said this is a very valuable instrument.

Dr. Joseph Price exhibited a

Forceps



for the complete closure of the trocar puncture in ovariotomy.

Dr. Parish exhibited a specimen of

Ovarian Tumor,

removed the previous day. The symptoms had been very peculiar, and the form of the abdomen was misleading, there being a deep groove across the hypogastric portion of the tumor. Numerous adhesions gave great fixity. These adhesions embraced the colon, parietes, and bladder, and were old and dense. Its rapid growth had raised a question of malignancy. A great portion of the tumor was solid.

Dr. Harris remarked that a microscopic examination of the tumor should be made. There had been great difficulty in diagnosis as to the origin and character of the tumor. A slight fluctuation could be detected in the lower portion under the use of an anæsthetic. There had been no uterine symptoms, and menstruation had been regular. The long fallopian tube crossed the tumor and made a deep constriction across its middle.

Dr. Baer did not think rapid growth a proof of malignancy. He had seen five or six cases of very rapid development; one in three months contained a bucketful of fluid. In none of these cases has there been any return or other sign of malignancy. The presence of papillomatous growths within the cyst is no proof of malignancy.

W. H. H. Githens, *Secretary.*

CLINICAL SOCIETY OF MARYLAND.

Stated meeting, held April 2d, 1886.

Dr. O J. Coskery read some notes from

A Case of Artifical Anus.

Dr. S. T. Earle called attention to a case similar to that of Dr. Coskery, reported in the *London Lancet* for May, 1885. The operation terminated fatally because of the puncture of the peritoneum. He asked if the plan advised of dissecting out the coccyx and turning back the rectum was not the preferable way of relieving these cases.

Dr. Randolph Winslow said it seemed to him that a cutting operation, the splitting of the anus to the coccyx and if necessary the removal of the coccyx, and the bringing down of the rectum and uniting it with the anus, would have been much more satisfactory in its results and much less severe on the child, than the method pursued in this case. Even if the bowel was fortunately entered by the trocar without injuring some of the neighboring viscera of the peritoneum, the difficulty of keeping a hole, tunnelled through the tissues, patent, was a very great objection to the method. As was well known, the parents of a child would be likely to neglect systematic dilatation, and the channel would close as it had done in the case reported three times already. When the mucous membrane of the rectum can be attached to the anus, this tendency to contrac-

tion is nearly overcome. If it is impossible to attach the rectal mucous membrane to the skin, a colotomy would probably be the preferable operation.

Dr. Coskery thanked Dr. Earle for calling his attention to the article in the *Lancet*.

The course pursued by him in his operation was the one desired by the parents of the child. He gave them their choice of the operations, and they united upon the least bloody one being done.

Were he called upon to do the operation again, he would adopt the plan of drawing down the rectum and uniting it to the external surface. He did not understand how Dr. Winslow could prefer a colotomy, when often by an incision two inches deep one could easily enter the rectum.

Dr. Earle, in speaking of the adhesions so often met as an obstacle to drawing down the rectum, gave as his opinion that they are not congenital, but are rather the result of manipulation with trocar and canula.

Dr. John Morris, while in the Dublin Rotunda, saw two cases of congenital imperforate anus. In one, there was a *cul-de-sac* leading a short distance into the soft tissues, and in the other there was but a depression at the point where the anus should have been. Both cases terminated fatally. The latter one was operated upon after the trocar and canula method, and at autopsy the bladder was found to have been punctured.

Dr. Joseph T. Smith then read a paper on

Albuminuria. (*See page* 676.)

Dr. J. H. Branham said that Dr. Smith's statement, that the cells covering the glomeruli had a secretory function, was contrary to what he had been taught. He took them to be only a flat epithelial covering, purely mechanical in their function. They acted, according to his ideas, as a filter, through which the watery and saline elements of the urine exuded. The cuboidal cells lining the tubes, he thought the true secretory elements.

Dr. I. E. Atkinson considered the comparative anatomy and physiology of the kidneys in different animals a very interesting study. For example, in birds, where there is no passage of true watery urine, the tubes are very long and convoluted, thus admitting of the reabsorption of the watery elements, and the passage of the solid constituents as solids; in fishes we see just the reverse; here there is no retention of the watery portion, and we find the tubes straight and simple, admitting of the passage of the urine just as secreted.

He believes the epithelium covering the tufts different from that lining the tubes; he does not consider it a true secretory structure, and does not think that the cuboidal cells of the tubes are the secretory elements of the kidneys.

Nitric acid and heat, or Heller's test of nitric acid alone, he thinks sufficiently accurate for all practical purposes in detecting the presence of albumen in the urine. Uric acid is sometimes thrown down, but this is easily recognized. A rather more convenient form in which reagents may be carried about, he finds in the test papers prepared by Parke, Davis & Co. They are handy, and he has found them tolerably accurate.

Dr. C. O. Miller referred to the experiments done upon the frog in Heidenhein's laboratory, in which it is shown that the epithelium covering the glomeruli have a true selective action. He thinks, however, that an objection of some weight may be made by the possible degeneration of the cells caused by the injection mass employed, and thus their true function altered.

Dr. Joseph Blum has employed the test papers referred to by Dr. Atkinson, and finds that, excepting the picric acid ones, they all deteriorate after a time.

Dr. J. H. Branham read a paper on

Perineorraphy.

Mary Johnson, col., age about 20 years, was confined on December 1st, 1886. The position was right posterior and the child was large.

The second stage of labor lasted for nine hours, and was finally teminated after great difficulty by the use of forceps. Notwithstanding great care exercised by a skillful operator, an extensive rupture of the parts occurred.

I first saw the patient about two hours after the labor was completed. The rupture included the perineum, the posterior wall of the vagina to the extent of two and a half or three inches, and an inch and a half of the rectum. It began in the middle below, and extended upward and to the right.

The tear through the perineum was ragged, and the sides were trimmed before bringing them together.

Three rows of sutures were used, one in the vagina, one in the rectum, and the other in the perineum. Some difficulty was experienced in introducing the high vaginal sutures, otherwise the operation was easy.

Before introducing the sutures the parts were thoroughly cleansed by bi-chloride solution, strength one in two thousand parts of water. Small iron wire was used for sutures.

After the operation a rubber tube with a number of openings in it was introduced into the vagina, the distal end being in a bottle of bichloride solution. This acting as a siphon carried off the lochia almost entirely. Parts were disinfected twice daily by fluid passed through this tube, bichloride being used part of the time. Bowels were closed by opium during first six days, liquid food being given. Patient did well, highest temperature being 102° on fifth day.

Sutures were removed on twelfth day, when good union was found, all the tear being healed except at the back part of ostium vagina and fourchette. The union was partly by first intention and partly by granulation.

What is the prognosis of primary operation in complete rupture?

Tait says: "If the case be seen immediately after the rent has been made, stitches may be applied without any preliminary paring; but this practice has never had a satisfactory result in my hands; for in all the cases where I have been called in to perform it, the tissues have been so bruised and the edges have been so ragged that a satisfactory union has never been effected save by a subsequent operation. It is, however, worth trying.

"Others have met with little better result. I attribute the success in this case to drainage and antisepsis, and think that unless such measures are carried out there is little chance of a good result. The vagina tends to dilate and the lochia to collect in it, when, unless some means are employed to prevent, it undergoes decomposition and prevents union.

Dr. W. Pawson Chunn: Was there any recto-vaginal fistula?

Dr. Branham: None whatever.

Dr. Chunn: What was the object of stitches in the rectum?

Dr. Branham: The rectum was lacerated for one and one-half inches, and the stitches were put there to restore this laceration. Their twisted ends were on the mucous surface of the rectum, and they remained in position for twelve days.

Dr. Chunn said his reason for asking so particularly about the stitches in the rectum, and the position of their twisted ends, was that such efforts were usually not so successful as Dr. Branham's had been. The plan usually adopted with success was to twist the wires on the mucous surface of the vagina.

Dr. Randolph Winslow thought Dr. Branham could scarcely claim much of the good result attained in his case as due to the antisepsis, which seemed to him to be very defective, being antiseptic only when the irrigations were being practiced, with an abundant opportunity for the entrance of germs in the intervals. After considerable experience in perineorrhaphy, Dr. Winslow had discarded wire sutures entirely, and now used antiseptic silk. The results were equally as good, the difficulty of introduction and removal of stitches very much less, and the comfort of the patient much greater. In cases in which women have been operated on twice, once with wire, the second time with silk, they express themselves strongly in favor of the latter. The continuous catgut suture is probably better than either, as the necessity of removing the stitches is thereby avoided.

Foreign Body in the Nose.

Dr. John N. Mackenzie relates a case of foreign body in the nasal cavity of a child, the removal of which was facilitated by the use of cocaine. Dr. Mackenzie regretted to be obliged to intrude upon the Society's time by bringing before them the much talked over cocaine, but in this case it proved itself of so much service that he considered himself justified in calling attention to its value in such cases. When he saw the child there was a bit of bone very tightly wedged between the corrugated mucous membrane. An attempt to remove it with forceps failed. He applied cocaine to the tissue in order that its power of causing contraction might lessen the pressure and enable him thus to remove the foreign particle. This effect was produced in a few minutes, and the bit of bone was easily removed.

Dr. H. Clinton McSherry had been in the habit of using cocaine with most happy results in obstinate cases of epistaxis.

Gonorrhœal Ophthalmia.

Dr. Samuel Theobald referred to a case of gonorrhœal ophthalmia that he had recently seen. When the patient presented himself the left eye only was affected, and had been so for three days. The lids were swollen, ecchymosis was present, and the cornea was sloughing at its upper margin. Right eye was at this time entirely free from this trouble. In spite, however, of every precaution, the right eye took on a similar condition. Treatment was at once instituted. The eye was painted over once daily with a 15 grains to ℥ of nitrate of silver solution, three times daily with a 2 grains to ℥ of the same drug. After each application the silver was washed away with sodium chloride solution.

Besides this, boracic acid solution was instilled every four hours, and atropia em-

ployed daily. The left eye is lost. The right eye is entirely under control. This the doctor attributes to prompt treatment. He thinks had the right eye gotten fairly under way, that it would have been destroyed.

Hemichorea and Hemiplegia.

Dr. Preston related a case of a girl whom he had recently seen. She had hemiplegia on one side and hemichorea on the other. The chorea came first, and was followed by the hemiplegia. He thinks the chorea was caused by a minute embolus, and the hemiplegia was the result of the consequent softening or by a second larger clot. He considered the case interesting, as probably shedding some light on the pathology of chorea.

Periscope.

Case of Intercurrent Hepatitis and Retained Gall-stones.

Dr. Alexander Napier thus writes in the *Brit. Med. Jour.:*

Mrs. W. T., aged 43, had been subject to occasional "bilious" seizures for at least six years, and to a tendency to prolapse of the womb for several years; for the latter affection she wore a pessary. She stated she had "gastric fever" twice, once twenty-three years ago, and again fourteen years ago; she was five weeks in bed in the last attack, not so long in the first.

With the exception of the "biliousness" referred to, there was no indication of grave involvement of the liver till June 21, 1884, when Mrs. T. suffered from well marked symptoms of hepatitis; acute pain in the right hypochondrium, enlargement of the liver, feverishness, nausea, and sickness, but no rigors, and no jaundice. She was confined to bed about two weeks. Mrs. T. then continued tolerably well, with occasional "bilious" attacks, always with want of appetite, till May, 1885, when she had another similar illness (apparently hepatitis), but much slighter, lasting only a few days.

In the end of July or beginning of August, 1885, she received a severe blow with a tennis-ball in the pit of the stomach. This caused intense pain at the time. From this date onwards the general indisposition, and the uneasiness in the region of the stomach, increased; there were a constant, dull, heavy pain in the hepatic region, entire loss of appetite, and progressive debility.

On September 10, 1885, the pain suddenly became very acute, and was accompanied by sickness and vomiting, which lasted for three days; this was followed by marked jaundice, the urine becoming very dark in color, and the stools white, or pipe-clay colored. The patient at this time was twelve days in bed, but the jaundice did not disappear till six weeks had elapsed. She then improved a good deal in general condition, and suffered no longer from headache or sickness, but there was still entire absence of appetite.

On November 18th, 1885, there was another sudden attack of severe pain in the hepatic region, which had been preceded for a day or two by an increased sense of uneasiness in the liver. It was then that I saw her for the first time. The attack was one of typical gall-stone colic; the pain was spasmodic, exceedingly severe, shooting up to the shoulder and through to the spine, causing the patient to cry out; it was accompanied by marked and severe rigors, and by vomiting. Pulse 96; skin cool; tongue whitish and moist. Relief was obtained from the use of morphine subcutaneously.

After the first night, the pain was not so severe; but the liver continued tender to pressure. The irritability of the stomach lasted for several days, only small quantities of liquid food being tolerated. Then vomiting ceased; the pulse rose to 120, and the temperature to 100° and 101°, for many days in succession; marked jaundice came on, with constipation, whitish stools, very dark (almost black) urine, headache, and nausea. The liver was tender to pressure over the left lobe and over the region of the gall-bladder; in the latter situation, a well-defined rounded mass could be felt. Hepatic dulness was not perceptibly increased in the axillary line, nor over the left lobe; but at the median edge of the right lobe, in the region of the gall-bladder, it came far past its normal limits downwards, exactly corresponding to the firm mass above referred to. The swelling was smooth, firm, and resistant, but gave no sense of fluctuation, or of rubbing when grasped.

Treatment consisted in the use of morphine at first, to relieve pain, the occasional administration of saline purgatives, chloride of ammonium, and pancreatized food, together with persistent poulticing of the hepatic swelling.

The patient was seen early in December by Professor Gairdner; he, without rejecting the theory of gall-stone, rather favored the view that we had to do with an abscess or tumor of some kind.

The patient's general condition gradually improved, though the mass projecting from the lower border of the liver continued rather tender to pressure, and quite unaltered in size, till January 8, 1886, when she had a severe rigor, vomiting, and acute hepatic pain; while the mass became distinctly larger, and much more tender. The skin and superficial tissues were freely movable over the swelling. Pulse 120; temperature not noted, but certainly not febrile. In a couple of days the pulse had fallen to 90, the sickness had ceased, and the local pain much diminished; this attack passed off without any jaundice.

On January 18th the patient complained much of severe darting pains, with considerable tenderness to pressure over the whole abdominal surface, not specially over the swelling, though this continued tender. These pains, probably connected with the formation of adhesions between the swelling and the abdominal parietes, lasted for several days, but yielded to persistent poulticing.

On January 22d she was ordered capsules containing ether and turpentine.

On January 25th there was slight vomiting once, and the capsules were stopped.

On January 27th very severe and persistent vomiting set in. Absolutely nothing, not even a drop of water or broken ice, remained in the stomach. The pulse ran up to 135, and the patient became exceedingly prostrate. She was supported by nutrient enemata.

On January 29th she was seen by Professors Gairdner and Buchanan, and was apparently sinking. The general abdominal pain had gone, but the tumor was unchanged in character, except that it felt more adherent to the skin. It was agreed that the swelling should be opened next day. Morphine, given subcutaneously, procured for the patient a fair night's sleep; and small quantities of milk and brandy were retained by the stomach.

On Saturday, January 30th, Professor Buchanan performed the operation.

Congenital Strictures of the Rectum in the Adult.

Prof. Trélat, in a clinical lecture at the Hôpital de la Charitè, calls attention to a class of cases of rectal stricture which have been little considered if not wholly overlooked by surgeons heretofore, viz., congenital strictures, the symptoms of which do not attract attention until adult life.

These strictures are valvular in form, thin and sharp, and are situated three to five centimetres from the anus, corresponding to the point of blending of the rectal cul-de-sac with the cutaneous depression in the process of development. He is disposed to regard all such strictures, so situated, as being congenital in their origin.

The mode of commencement of the grave symptoms is various. Sometimes a patient reaches the age of forty or more years without having experienced the least irregularity in the intestinal functions; sometimes there are in infancy transient, intermittent phenomena, which become serious at a remote epoch. A third category includes those in whom during their whole life there are more or less serious intestinal disorders.

While he recognizes the difficulty or impossibility of satisfactorily accounting for the appearance of these manifestations, or their intermittent character when the causative lesion is a permanent one, he calls attention to the fact that this is by no means an exceptional case in this regard—that there are various other affections of congenital origin which demonstrate their presence only in adult life.

As to this particular feature it is easy to understand that during early life it is simple, extensible, with no induration, perhaps even less close and narrow than it will be later. The abdominal muscles have all their vigor, and the intestinal, biliary and pancreatic secretions are abundant, making all the physiological conditions for easy defecation. But as age advances, an induration of the valvular fold takes place, the muscles become weakened, the intestinal walls are less lubricated, the fæcal mass less softened, and the lesion, previously innocent, produces a trouble more and more pronounced.

Thus there may be inflammatory troubles, and consecutive fistulæ. The site of these last is constant: they are situated above the stricture, and are due to the valvular lesion itself.

This complication is frequent, but there are others more serious, whose course is the same; the obstruction offered to fœcal matter by the stricture, and the changes of the

rectal mucosa above the valvule, create a constant inflammatory state which results in perirectitis, adenitis, gangrenous phlegmons of the pelvis, finally interstitial nephritis and sclerous hepatitis, which seem to be consecutive to these peri-rectal phlegmasias.

Prof. Trélat urges the importance of early diagnosis, inasmuch as the lesion itself and its effects become more and more serious as time advances. He says that examination by rectal touch should be practiced on the first indication of obstruction.

The prognosis is grave, by reason both of the serious accidents which the lesion causes and on account of the nature of the treatment demanded.

The best mode of treating these affections, even when discovered early, Prof. Trélat does not think has yet been established.

Hodgkin's Disease and Its Consequences.

Dr. John Taylor thus writes in an English journal:

The following case, having a fatal issue, presented peculiar features, which may probably be worthy of reccord:

C. S., aged 14, had not been in good health for some months, although there was nothing in particular to cause anxiety. He had been observed to be out of breath on exertion, to have lost his appetite, and to be frequently craving for water. He had never suffered from ague or fever; he had no cachexia, was fairly nourished, and had never had any hemorrhage from his nose or gums. About a fortnight before the accession of marked illness, he got into trouble in snowballing, and this led him to suffer a somewhat severe chastisement. The symptoms attending his last few days of illness were so unusual and unaccountable that it was suggested that ill-treatment might have caused or accelerated the fatal termination; moreover, exaggerated rumors were abroad as to the injuries he had received. Under these circumstances, it was deemed unadvisable to certify without referring to the coroner, who very properly directed an inquiry to be held and a post-mortem examination to be made.

C. S. was first seen on December 21, by my partner, Dr. Hoar, who found him suffering from gastric disturbance, coated tongue, foul breath, etc., but with a normal temperature, and no symptom of an alarming character. On the 23d, his urine was noticed to be pinkish in color, from admixture of blood, and, of course, loaded with albumen; but he was cheerful, sat up in bed, and played the flute; vomiting supervened. On the 25th, convulsions set in, and on the same day he died.

The post-mortem examination was performed by Dr. Hoar and myself on the 27th. There were two bruises observed on the left arm, but no further evidence of external injury. In the anterior mediastinum was found a diffused ecchymosis; the heart-substance was pale, but apparently healthy; both ventricles were full of blood. The pericardium contained about two ounces of serum; the lungs were crepitant throughout. On opening the abdomen, the spleen was noticed to be enlarged, and, on further examination, it was found to be four or five times it normal size; the liver was enlarged, extending about three finger-breadths below the margin of the ribs. The stomach and intestines showed no evidence of disease, but there was a general and considerable enlargement of the mesenteric glands. On the posterior surface of the right kidney were two ecchymosed patches; its pelvis was full of extravasated blood, as was also that of the left kidney. On removing the calvarium, the dura mater was found healthy; the vessels of the surface of the brain were congested. There was no evidence of inflammation within the skull, either past or recent. The fourth ventricle was full of extravasated blood. Both lateral ventricles were filled with a large and soft coagulum, breaking up the brain-substance in its neighborhood; the brain itself was healthy. The superficial lymphatic glands throughout the body were, more or less, enlarged and indurated; the submaxillary on both sides, the concatenate, a row of inguinal glands on each side, stood out prominent and distinct; the deep glands in Scarpa's triangle were also affected. On section, the glands presented a greyish surface, and appeared to be simply hypertrophied; no morbid deposit in their substance was discernible.

The Seasonal Prevalence of Pneumonia.

We are indebted to Dr. Seibert of New York for having more than once directed attention to the close relation existing between those meteorological conditions which favor catarrhal affections and the occurrence of acute (fibrinous) pneumonia. At the present day, when the specific nature of this disease is receiving so much confirmation, it is specially useful to have the question viewed from another side. In his latest contribution to the subject (*Berl. Klin. Wochenschr.*, 1886, No. 17), Dr. Seibert affords conclusive evidence of the above-named con-

nection. His material was obtained by a collective investigation of returns furnished by members of the New York Medical Society, from March 1st, 1884, to March 1st, 1885. They comprise 768 cases of primary pneumonia, distributed in the various months as follows: January, 71; February, 140; March, 103; April, 73; May, 55; June, 37; July, 26; August, 25; September, 43; October, 62; November, 65; December, 78. A comparison with the average temperature of these months shows a striking correspondence between the lowness of temperature and prevalence of pneumonia; and a similar correspondence is manifested with respect to rainfall, except in the summer months, when, in spite of great humidity, there was a minimum of pneumonia. It is also shown that the prevalence of bronchial catarrh closely coincided with that of pneumonia. Dr. Seibert has not, however, been contented with these general monthly returns, but has placed side by side the results of daily meteorological observations and the date of occurrence of cases of pneumonia during each month of the year. The chart compiled from these data for the month of February will be found in his paper; and it is remarkable how closely the onset of pneumonia follows upon days in which there were combined low temperature, excessive humidity, and high winds. Without attempting to give examples of these relations, it must suffice here to allude to the conclusions at which Dr. Seibert arrives. These results are to the effect that the varying prevalence of the disease can be explained by certain meteorological states which favor its occurrence. These conditions are a low and falling temperature, an excessive and increasing humidity, and high winds. When any two of these factors concur, pneumonia prevails to a greater extent than when only one of the factors is present; whilst if all three factors are in operation, then pneumonia is exceptionally frequent, the frequency lasting as long as the meteorological conditions obtain. The same states of weather favor catarrh, and catarrh predisposes to pneumonia. That pneumonia is more prevalent in spring than in autumn is due partly to the greater liability to exposure after residence in hot and ill-ventilated rooms during the winter, as well as probably to the greater humidity of spring. Finally, the author does not wish it to be inferred that these meteorological conditions are the sole factors at work in exciting pneumonia; his opinion rather is that by exciting catarrh they render individuals more vulnerable and susceptible to the influence of the pneumonic virus. In this way his observations can still be made to harmonize with the doctrine of the specific nature of pneumonia.

Observations on Feigned and Artificial Eruptions of the Skin.

Dr. W. A. Hardaway thus concludes an article in the *St. Louis Courier of Medicine*, for May:

In conclusion, I would beg leave to indicate a few of the points which should be borne in mind in making the differential diagnosis between the so-called feigned and artificial eruptions and the substantive diseases of the skin. In the first place, we should ascertain the antecedents of the patient, and take particular note of the present condition. Secondly, we should discover if the patient had ever suffered from any skin disease before, and whether the patient had been or was at the time making use either locally or internally of any medicinal preparation. We should compare the lesions present with otherknown eruptions of the skin, and make particular note of any anomaly. We should investigate closely the local expressions of the disease, for instance as regards infiltration, itching, burning, etc. It must be borne in mind that most eruptions produced with intent to deceive, generally occupy situations most accessible to the patient, and in the majority of cases, in right-handed persons, are apt to be on the left side of the body. It would be tedious to enter into the minute details of the differences between these feigned eruptions and those due to disease, as, for instance, how a pemphigus bleb will have a certain definite outline, and a bleb produced by nitric acid is apt to be jagged and irregular or linear, but I think enough has been given to show in a general way the cautions to be observed in coming to any conclusion in regard to a suspicious eruption. The late Dr. Tilbury Fox has pointed out that so far as the simulated skin affections are concerned they generally are of the following forms: The eruption is in erythematous or excoriated patches, such as may be produced by rubbing or by mustard; or bullous, or pustular, or more or less deeply ulcerative, and such as could be caused by the application of cantharides, croton oil, or some corrosive acid; or such an eruption as could be brought about by the constant forceful use of the finger-nails; or it is a pigmentation—*e. g.*, simulating chromidrosis, produced by black lead, candle black, grease, and other compounds.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The *Medical Review*, of St Louis, appears with an advantageous change in appearance. It is issued under the supervision of the Medical Press Association, and is a valuable periodical.

——Under the title "A Year's Work on Laparotomy," Dr. William Goodell, of Philadelphia, gives a brief resume of the number of cases he has operated upon within this period, with statistical tables, etc.

——The annual report of the Cincinnati Sanitarium for 1885 shows the institution to be in a flourishing condition. The superintendent is Dr. O. Everts, College Hill, Ohio.

——The progress of Electrolysis in Surgery is briefly set forth by Dr. Robert Newman, of New York city, in a paper of eight pages.

——One of the recent articles on cocaine is by Drs. J. Baratoux and E. J. Maure (*De la Cocaine*, Paris, 1885). It is the reprint of an article read before the Société Francaise d' Otologie et de Laryngologie.

——The First Annual Report of the Pathological Department of the Norristown Pennsylvania State Hospital for the Insane, by Drs. Dercum and Reel, contains the report of a number of autopsies of great interest to alienists.

——Dr. Henry F. Campbell, of Augusta, Ga., forwards a reprint of his article read before the American Gynecological Association on the value of the genu-pectoral position in impeded uterine reduction, and in the prolonged nausea and vomiting of pregnancy.

BOOK NOTICES.

The Methods of Bacteriological Investigation. By Dr. Ferdinand Hueppe. Translated by Hermann M. Biggs, M. D. Illustrated. 8vo., clo., pp. 218. New York: D. Appleton & Co., 1886.

The author of this work, Dr. Hueppe, is one of the most brilliant disciples of Koch, and in this volume he has given in detail the methods employed in the laboratory of that celebrated bacteriologist. He indeed claims to do more, and to present a historical survey and criticism of the whole subject. But it is quite evident that this claim is not well founded, as he scarcely goes beyond the Germans in his quotations, and passes over the French writers generally without any mention. It is therefore a description of the Koch plans, and little more.

He begins with the forms of bacteria and the technique of microscopical manipulation. From these he passes to culture methods and inoculations, to general biological problems, and to special hygienic investigations. As a hand-book in this novel and promising branch of science it is one of the best which has yet appeared, and should be in the library of every student of the subject.

Seventh Annual Report of the Board of Health of the State of Illinois. 8vo., pp. 623. Springfield, 1885.

This compendious report gives full details of the proceedings of the Board, vital statistics of the State, decisions under its laws regulating medical practice, information on medical education in the United States and Canada, etc., etc. These materials are carefully arranged and presented, and some of them have already been referred to in other connections. Altogether, the volume is a very satisfactory one.

Proceedings of the Nebraska State Medical Society. 17th Annual Session. 8vo., pp. 385. Lincoln, 1885.

A favorable impression is created by this volume through the neatness of its manufacture, and this impression is strengthened by an examination of its contents. The proceedings of the meetings of the Society are chronicled, and a number of reports and original articles of decided merit are added. A somewhat new feature is the prominence given to the reports of delegates from other states and from foreign countries. The addition is a good one, and tends to foster the comity of science which every one should desire to see maintained.

Drainage for Health, or Easy Lessons in Sanitary Science. By Joseph Wilson, M. D. Second edition. Illustrated. 8vo., cloth, pp. 72. Price $1.00. Philadelphia: P. Blakiston & Co., 1886.

The author in these chatty and agreeable pages conveys a large amount of instruction in so pleasant a style that one insensibly continues the perusal of his sentences, no matter where one opens the volume. He discusses land drainage, the drainage of cities and of houses, and adds some sound advice about plumbing. The present edition has received important additions, and will be found a valuable hand-book to the general reader as well as to the physician.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

SULPHATE OF SODIUM.

Especially in our country, whenever a neutral salt seems indicated as a purgative, Epsom salt—sulphate of magnesia—is usually the remedy employed, while sulphate of sodium — Glauber salt—is neglected. One reason for this may be found in the fact that Glauber salt is very cheap, and that it is used mainly in horses. Not long ago we advised a patient to take Glauber salt, but when the patient asked his apothecary for it, the latter ridiculed the idea, and said that this salt was used for horses only.

Epsom salt cannot be administered to young children, because its action on the delicate mucous membrane of the alimentary canal of the young is too harsh; but Glauber salt can be given with immunity. This fact alone should convince everybody that in most cases sulphate of sodium is preferable to sulphate of magnesia.

Nothnagel, a year or two ago, investigated the action of neutral salts on the intestines. He found that sulphate of sodium—Glauber salt—was the mildest of all; that it first caused a very slight redness, and later induced depletion by emptying the congested capillaries and producing a slightly watery stool. In the inflammatory intestinal disorders of childhood, as for instance in cholera infantum, if administered early in moderate doses, it acts almost as a specific, while sulphate of magnesia induces a severe congestion of the intestinal mucous membrane, and generally destroys the epithelial lining. Experience has proved this observation to be correct, for, generally, wnenever especially a larger dose of Epsom salt has been given, the patient will suffer from constipation, or at least from sluggishness of the bowels, for several days afterwards.

The action of Glauber salt is so certain and at the same time so much a true laxative —not causing congestion and not injuring the epithelial lining—that a much smaller dose is generally needed than in the case of the magnesia sulphate. In most cases from one-half to a teaspoonful, if administered to an adult, largely diluted with water—as all neutral salts should be if the intention is purgation—one hour before breakfast, will induce one or two motions of the bowels about half an hour after the meal, and this result will be brought about without the least griping and without any after-effect, as constipation, so often observed as a consequence of the magnesia salt.

We publish these remarks mainly for the benefit of those who imagine, because Glauber salt is used by veterinary surgeons, that

its use would not be indicated in the case of human beings, for it is used for horses only on account of its cheapness. In every case it should be preferred to Epsom salt, for the reasons given.

METALLO-THERAPEUTICS.

Burge first made the interesting observation, that local anæsthesia, especially in those hysterical females who are inclined to trance and similar conditions, may at once yield to the local application of certain metals. That metal which in the individual case caused a momentary disappearance of the anæsthesia, or produced any irritation or change in sensation on local application, is then administered internally, and is apt to cure the anæsthesia permanently, if thus given. The art thus to discover the metal indicated, is called Metalloscopy, while the treatment based upon it is understood by the name of Metallo-therapeutics. Prof. Engel of this city, while reporting an interesting case thus treated, gave a full explanation of this branch of medicine in an article published in the MEDICAL AND SURGICAL REPORTER about two years ago.

Dr. Moricourt (*L' Union Méd.* 14, '86) at the occasion of a meeting of the Academy of Science in Paris, reported the results of his investigations into Metallo-therapeutics. He has come to the following conclusions:

Some neuropathics suffer from local anæsthesia, which does not disappear on external application of metals. In such cases the return of sensibility may be achieved by the subcutaneous injections of certain mineral salts.

Individuals laboring under spontaneous lethargy, catalepsy or somnambulism, also such as may be hypnotized or mesmerized, react in nine cases out of ten on copper or gold, or on both. These metals bring back sensation in these cases.

To discover the metal most indicated in the case, and also the dose best suited and to be employed internally, pieces of metal are placed in rapid succession on the hand or the forearm of the mesmerized person. The one producing most sensation of formication or the like is the one indicated. The dose for internal administration of the same metal must be the less, the more intense the sensation caused by the local application. In one patient a pill containing the sixth of a grain of oxide of copper caused vomiting and diarrhœa. For subcutaneous injections solutions of $\frac{1}{500}$ or $\frac{1}{1000}$, dose 5 to 10 minims, are employed. Citrate of iron and nitrate of silver are the metals most generally used for this purpose.

COFFEE AND PRURITUS.

Especially the pruritus ani and pruritus vulvæ are very annoying complaints, which not seldom make those suffering from them feel wretched. The observation has frequently been made that a rich and highly seasoned diet, sometimes even the eating only of certain aliments, decidedly aggravates the intolerable itching. But recently Brown-Sequard made a discovery which will surprise many a practicing physician, and serve to explain the often so stubborn character of this troublesome disease. He found that in several instances the drinking of coffee directly produced the pruritus.

Two very nervous patients were especially observed by him for the purpose of investigating this effect of coffee. He convinced himself in both cases that between the appearance of the itching and the drinking of coffee existed a definite relation, so that whenever the patients had taken a larger quantity of coffee than they had been in the habit of drinking, the pruritus at once increased in severity. Still more to prove the relation of cause and effect between the coffee and the pruritus, he forbade the use of coffee totally. The result was as expected by him; the itching in both instances ultimately vanished completely.

If we remember that the vast majority of patients habitually use coffee, at least for breakfast, and provided that this auxiliary aliment produces pruritus, we cannot wonder why the disease proved so rebellious in so many cases. Even should coffee not directly cause the complaint, it surely aggravates it, and it may be well, therefore, totally to interdict its use in cases of pruritus ani or vulvæ.

MEDICAL ASPECTS OF SOCIAL QUESTIONS.

If the influence of the medical profession is to be exerted in the manner most effective for the good of humanity, it must be directed to those sociological problems which most nearly concern the perpetuation of the species. Yet, strange to say, this is so little appreciated, that no questions in sanitary and preventive medicine are less discussed than these.

It would not be difficult to put one's finger on the reason for this. Through the influence of dogmatic teaching and false notions of decorum, these questions are laid

under a *taboo*, even in the medical world. Absurd assertions in regard to them continue to pass unchallenged, and though the individual physician may entertain sound and liberal views about them, he fears to express himself, lest his business suffer.

The questions we refer to are such as the propriety of limiting child-bearing, of licensing and registering *maisons de tolerance*, of providing against the spread of contagious specific diseases by periodical inspection, of counteracting the increase of celibacy by judicious provisions with regard to marriage, so as to make it less of a burden than it now is in this country, of facilitating divorce, of providing for the greater independence of of women both in and out of marriage; and there are many other vitally important problems of a similar character.

We had hoped that the increase of enlightened women physicians would have led to broader views on these topics—that some of them would have come forward with knowledge and courage to advocate the needed reforms in these matters, reforms so essential to women securing the influence which they should exert in the social status of the future. But we have looked in vain. No one knows better than women themselves the heavy burden of frequent parturition; but how many women physicians have come forward to denounce it? They, too, should be those to take an active part in the medical control of public women; but no one has so far even advocated such control.

The near future should bring bolder and truer views on these topics, and they should be studied wholly apart from tradition or dogma, and prejudice and fear.

Notes and Comments.

Inversion of the Uterus.

Dr. M. G. Biggs reports this case in the *Brit. Med. Jour.:*

"It was a middle-aged multipara, whom I had attended once previously, and on that occasion the labor was a simple one. A month or two ago I again attended her; the child was born, and I placed my hand over the uterus, and felt it contracting; but as the placenta did not come, and the patient informed me 'that once before the after-birth had grown to her side, and the doctor had been obliged to remove it,' I asked the nurse to place her hand over the abdomen, intending myself to introduce the hand and remove it. On introducing two fingers, however, into the vagina, I found a good part of the placenta already there, and so used traction on the cord, which readily brought away, not only the after-birth, but also a large body, which proved to be the inverted uterus; the membranes seemed attached to the surface, and these I pulled off. On placing my hand on the abdomen, no uterus could be felt, and the fingers could be passed well down into the pelvis, owing to the thin abdominal walls; but no trace of a contracted uterus could be felt. My patient now became very pale, her pulse almost ceased, and she said she was going to faint. I gave her a teaspoonful of brandy, and, feeling that no better time than the present could exist for reduction, as the faintness would relax the muscular tissues, I placed both hands against the fundus, and pushed it back into the vagina; then, with three fingers of the right hand, I followed the fundus up the vagina, and had the good fortune to effect complete reduction without any trouble, beyond a certain amount of pressure. There was no bleeding. The contracted uterus could now be felt by abdominal palpation. The faintness passed off, and my patient made an usual recovery.

Albuminuria Probably Consecutive to Scarlet Fever; Sudden Death.

Dr. Descroizelles, Physician to the Children's Hospital, Paris, recently had under his care the following case, which presents some features of interest. The patient was a boy, aged 12. Three weeks before admission, he was seized with scarlet fever. This, according to the statement of his relatives, followed the usual course. A slight eruption appeared, and was preceded by sore-throat. The eruption quickly passed away. The child was kept in bed, but seemed quite well until seventeen days subsequent to the appearance of the fever; it was then observed that both cheeks were swollen. Three days later, he was admitted into the hospital. His face was œdematous, but there was complete absence of fever. For some days he had passed very little urine, namely, from 120 to 130 grammes in about twenty hours. It contained a very large proportion of albumen. The child was kept in bed, and his limbs were enveloped in cotton-wool. His face and extremities remained slightly œdematous. There was no fever, nor dilatation of the pupils. The lungs and heart appeared normal. The quantity of urine passed was scanty, as before admission, and contained a large proportion of albumen.

On January 22, two days after admission, the child vomited slightly, and said he felt uncomfortable, but could not define his sensations. All of a sudden, he called out, became insensible, and died. The necropsy was made forty hours afterwards. It was observed that the pericardium was healthy, but a thick layer of adipose tissue covered the inter-ventricular groove at the apex of the heart. The right lung presented an area of hepatization; the liver was enlarged, and of a violet color; but there were not any lesions which explained the boy's death.

Iodoform in Chronic Catarrhal Metritis.

In atonic external ulceration, iodoform has proved one of the most effective curative agents. Dr. Kugelmann of Berlin employed this drug also in fistulous passages, and when ulceration attacked internal cavities, as the mouth, the nose, the rectum, etc. The great success which he achieved has induced Dr. Weissenberg of Coblenz to test the efficacy of iodoform in chronic catarrhal metritis. The results published by him in the *Berlin Klin. Wochen.* 17, 1886, have been very favorable. To get the remedy in a sufficient quantity into the internal cavity of the uterus, Weissenberg had a kind of catheter constructed, bent to suit the curvature of the uterine neck, and through this he pushed the iodoform by the aid of a kind of piston or ramrod into the uterus.

All the cases of chronic endometritis, whether attended by more or less extensive ulcerations or not, at once improved after the very first application, and in most instances but three or four such applications are needed to establish a radical cure. In no case were any bad after-effects noted, the enlargement of the womb rapidly disappeared, and the increase in the catamenial flow ceased. The method surely deserves further trial.

Digital Examination of the Nasal Chambers and Denudation of the Turbinated Bones in the Treatment of Chronic Nasal Catarrh.

In the varieties of chronic catarrh in which the discharge is purulent or composed of crusts, the mucous membrane covering the middle turbinated bones will be found to be thickened and softened. In the atrophic form of the disease, the inferior turbinated bone will participate in this condition, and the entire interior of the nose may be lined with membrane which is so far changed from the normal type as to be scarcely recognizable by any of the characters which anatomists employ in its description. Dr. Harrison Allen, in an article on this subject in the April number of the *American Journal of the Medical Sciences*, states that he has for some time been in the habit of studying these altered structures as though they were periosteum and bone respectively, and of being guided in their treatment by principles similar to those which are relied upon in treating the diseases of the periosteum and adjacent tissues. In a word, digital examination of the interior of the nose can be made, the nasal muco-periosteum divided or removed, the bone scraped or excised, with the most encouraging results. Dr. Allen urges that the digital manipulation is an aid to diagnosis of nasal affections, and that the act of denudation is a safe and useful procedure.

The Vesiculæ Seminales and Skene's Tubes,

Mr. J. Bland Sutton, in an important contribution to the *Journal of Anatomy and Physiology* for April, appears to have proved, from careful dissection of the genito-urinary tract in seventy cows, that Skene's tubes, and the pair of urethral glands with which they are connected, represent the vesiculæ seminales and their ducts in the male. The orifices of Skene's tubes may frequently be detected on the margin of the meatus urinarius: and Böhm has described catarrh of the tubes, sometimes of gonorrhœal origin. Max Schüller has definitely traced the communication of Skene's tubes with a pair of glands in the upper part of the urethra. Sutton denies that the tubes are distinct from Gartner's ducts, and has found a glandular diverticulum springing from each, just above its termination in the wall of the vagina in the cow. Precisely the same condition exists, but in a far higher grade of development, in the terminal part of the vas deferens, the homologue of Gartner's duct in the male, and the diverticulum in this case is the vesicula seminalis. In the human female, Skene's tubes and their glands are entirely urethral, and not connected with the vagina, as in the cow.

On Strychnine in Dipsomania.

In the *Vratch*, No. 10, 1886, p. 177, Dr. U. M. Popoff, of St. Petersburg, states that, guided by the works of Magnus Huss, Luton, Dujardin-Beaumetz, and others, he employed nitrate of strychnine in two typical cases of dipsomania, and obtained strikingly successful therapeutic results. In one of the patients (a very gifted man of letters, aged 40), the

alkaloid was administered under the skin, in the dose of $\frac{1}{30}$th of a grain at first (during a drinking bout) daily, then every other day, then twice a week, etc. The patient ceased to ask for drink after the second injection: within the next two days, various morbid phenomena (headache, weakness, discomfort, etc.) disappeared. On subsequent occasions, a few injections of $\frac{1}{60}$th or $\frac{1}{45}$th of a grain of strychnine rapidly removed craving, anxiety, irritability, agoraphobia, and other premonitory symptoms of a threatening dipsomaniac attack. The patient each time rapidly improved in all regards, and felt desire for work and society. In another patient, dipsomania disappeared under the internal administration of strychnine, the alkaloid being given for the first two weeks in doses of $\frac{1}{30}$th of a grain, and for another two weeks in that of $\frac{1}{60}$th, twice a day, in pills.

Milk Diet in Chronic Nephritis.

In view of the fact that milk diet had been emphatically recommended by many observers, Dr. Trubatcheff undertook a series of comparative observations on four patients with chronic nephritis (three with the parenchymatous, one with the interstitial form), each of whom received ordinary hospital diet during one period, and either mixed or pure milk diet during a subsequent period of equal duration. The results are as follows:

1. An exclusive milk diet invariably led to a marked increase of the daily and percentage amount of albumen in the urine.
2. The patient's weight fell considerably, without any marked change in his dropsical state.
3. A mixed milk diet also led, in the majority of cases, to an increase in the daily and percentage amount of albumen excreted.
4. Neither pure nor mixed milk diet produced any marked increase in the amount of urine.

The author is now studying the assimilation of protein by nephritic patients receiving milk diet, which study will enable him to settle the question of the treatment.

The Influence of Diabetes on Gestation, Parturition, and Menstruation.

According to many authors, diabetes renders women sterile. Six cases studied and treated by Dr. Lecorché contradict this theory. His six diabetic patients were delivered of children at term, but they were all delicate. One child died two days after its birth; another, when 21 months old, became hydrocephalic, with polydipsia. There was no sugar in its urine. A third had a double hydrocele, and was also hydrocephalic, and could not live. Dr. Lecorché concludes that diabetes does not render women sterile. When they do not conceive, it is uterine lesions, resulting from diabetes, that cause their sterility. Diabetes has direct influence on the process of gestation, impairs fœtal nutrition, and is favorable to faulty development, especially hydrocephalus. Diabetes often produces dysmenorrhœa and amenorrhœa. Early menopause may result from an overlooked diabetes. The menses may re-appear when the sugar disappears. According to Dr. Lecorché, metrorrhagia in a diabetic patient indicates a co-existent uterine affection, and is not the result of diabetes.

White of Egg in Obstinate Diarrhœa.

From the *Allg. Med. Cent. Zeit.*, we learn that Celli has recently called attention to the curative properties of the albumen of hen's eggs in severe diarrhœal affections. In a discussion before a medical society at Rome, he advocated its use, and related two cases of chronic enteritis and diarrhœa, which, having resisted all treatment, speedily made complete recoveries under the use of egg-albumen. The same diet is strongly recommended in the diarrhœa accompanying febrile cachexia and in that of phthisis. In two cases of diarrhœa dependent upon tertiary syphilis, it was found of no avail. On post-mortem examination, diffuse amyloid degeneration of the arterioles of the villi was found in these cases. The whites of eight or ten eggs are beaten up and made into an emulsion with a pint of water. This is to be taken in divided quantities during the day. More may be given if desired. The insipid taste can be improved with lemon, anise, or sugar. In case of colic, a few drops of tincture of opium may be added.

Treatment of Night-sweats.

In the *Gazette Médical de Paris* we find two suggestions as to the relief of phthisical and other night-sweats. They are both simple enough, and certainly merit a trial.

In the first procedure it is directed that the trunk be sponged or rubbed with a mixture of four parts of tincture of belladonna to thirty parts of water. The lotion is best applied by pouring it into the hollow of the hand and bathing the body an hour or two before the expected sweating.

In fifty cases cited, but one failure to suppress the perspiration is recorded.

The second method consists in sponging the body of the patient with a solution of eight grams of chloral hydrate in one goblet each of water and whiskey. If the sponging alone does not suffice, the patient should wear a shirt that has been dipped in the solution and then dried at a moderate heat. In the non-phthisical night-sweat of children this device is said to yield excellent results.

Iritis Serosa Occurring Rapidly after Wound of Opposite Eye.

Before the Ophthalmological Society of the United Kingdom, Mr. Edgar Browne narrated the case of a gentleman struck in the left eye by a branch. He traveled to Liverpool from Cumberland; and when first seen the cornea was hazy, the iris was muddy, and in the anterior chamber was a thorn, which had wounded the periphery of the iris. The thorn was extracted next day, but the lens was already opaque on the surface, and the iris was covered with lymph; that night he had violent pain in the right eye, due to iritis. This iritis of the right eye fluctuated, and keratitis punctata appeared in both eyes, though the wound healed well. He eventually recovered, with good vision. Mr. Browne believed that the keratitis punctata was not due to the injury, but had arisen independently, or had, at the most, but a very indirect connection, setting up, perhaps, atrophic disturbance, which determined the onset of an impending keratitis.

Cocaine in Hay-fever.

Dr. Seth Bishop, in a lecture recently delivered by him at the Chicago Medical College, alluded to the wonderful effects claimed for cocaine in the treatment of hay-fever. He had made a certain number of personal observations, and summed up his conclusions as follows: First, it was not to be expected that a drug with so ephemeral an influence should be successful in permanently arresting an affection of the nature of hay-fever. Secondly, undoubted relief often followed the application of a spray of the solution, but it required to be renewed every hour or two, if the effect were to be maintained; and such repeated applications were liable to be followed by the absorption and physiological effect of the drug. Thirdly, it produced an anæmic and contracted condition of the mucous membrane, followed, after some time, by congestion and hyperæsthesia, the suffering from which more than compensated for any relief obtained. Finally, this reaction was much more marked in some individuals than in others.

Hereditary Tremors.

Before the Medical Society of London, Dr. Samuel West read the history of a cabman who had suffered since his earliest years from constant tremors, not affecting the tongue, eyes, or facial muscles. The most interesting feature of the case was that, on inquiry, his mother and grandmother appeared to have been subject to similar tremors. Further, the patient was one of ten children, and all of them suffered in a varying degree from the same thing, and the condition had been re-produced in his own six children.

Dr. Stephen Mackenzie alluded to a similar case, except that the history had not been so carefully ascertained.

Dr. Angel Money mentioned the frequency with which chronic chorea was transmitted, and the liability on the part of motor disorders to be handed down to the offspring.

Hydrophobia in Austria.

Dr. von Frisch, who was lately sent to Paris by a Vienna committee to inquire into Pasteur's system of inoculation against rabies. has given an account of his researches in a public meeting at the Town Hall. He unreservedly commended Pasteur's system, urging that it should at once be adopted by the medical profession in Austria. Giving some statistics on hydrophobia, he said that, in Austria, there had been 135 deaths from this cause in 1874, and 132 in 1875. In 1882, the mortality declined to 77, the lowest figure on record. Dr. von Frisch warmly advocated the compulsory muzzling of dogs in the streets, and thought it a matter for congratulation that the number of dogs should be decreasing. There was now, he said, but one dog in Austria for every section of 116 inhabitants.

Obstinate Sciatica Cured by Massage.

Dr. Berne states in the *Journal de Médicine de Paris*, that every therapeutic means failed to improve a case of sciatica of the left lower limb. The patient was 53 years of age, neither gouty nor rheumatic, but had suffered from piles since the age of 18. After the fifteenth massage, the patient could walk. After the fiftieth, he was able to resume his usual avocations, and could take long walks.

Correspondence.

Why Bright's Disease is so Fatal.

Eds. Med. and Surg. Reporter:

The term Bright's disease is used to indicate an organic disease of the kidneys, and was adopted in honor of Dr. Bright, who a half century ago called the attention of the medical profession, in a manner never before so clearly elucidated, to this morbid condition of the kidneys. The word *Albuminuria*, which means albumen in the urine, is also used to designate this same disease of the kidneys; but Bright's disease is the term most generally used to denote this malady of the kidneys.

THE APPROACH OF THE DISEASE.

In medicine the disease is divided into the acute and chronic; that is, when the disease is sudden and violent it is called *acute;* and when slow and insidious in its approach it is called *chronic;* and whether it comes in the acute or chronic manner, it is always a serious and dangerous disease, sometimes destroying life in a few weeks, or making existence intolerable by its continuance for months or years.

An acute attack sets in with a chill, followed by fever, pain in the loins and back, attended with a marked diminution in the scanty passage of urine, loaded with albumen, which also presents a smoky or dark-brown appearance. Accompanying these symptoms are headache, dry, hot skin, furred tongue, vomiting, and loss of appetite. When an individual suffers from these symptoms, his physician should lose no time in ascertaining the extent of the disease of the kidneys, for upon a correct diagnosis, and careful and proper treatment of the acute stage of the disease, depends the safety of the patient. When early recognized and skillfully treated, two-thirds of all cases of acute Bright's disease get well in a varying interval of weeks or months; but however early detected or skillfully treated, one-third will prove helplessly and hopelessly fatal.

CHRONIC BRIGHT'S DISEASE.

The chronic form of this disease is more fatal than the acute, for it is both insidious and symptomless in its approach and progress, and the rule is for it to terminate fatally. Two-thirds of the cases of chronic Bright's disease are caused by the habitual use of the compounds of alcohol, and no case thus caused has ever been known to get well while the patient continued to habitually drink alcoholic stimulants. The cause of the uniformity in the fatality of chronic Bright's disease is entirely attributable to the nature of its silent and insidious approach. Its presence is not suspected by the patient by any symptom that it presents. Whatever symptoms may manifest themselves, are those of ordinary dyspepsia; and it is not until the disease has made an incurable advance that the patient calls the attention of a physician to his condition. Then it is too late. The disease has progressed to such an extent that it has almost destroyed the functions of the kidneys; and all the physician can do is to smooth the way of the patient to a very near death.

It is this symptomless approach of chronic Bright's disease that beguiles the patient and leads him to suppose there is nothing more the matter with him than ordinary dyspepsia, and in obedience to this deception he loses the valuable time necessary for the treatment of the disease.

THE GREAT PREVALENCE OF BRIGHT'S DISEASE.

The customs of modern society, and the predominance of the habit of dram-drinking, have caused the great prevalence of chronic Bright's disease; and this fact is not only well known to the medical profession, but familiar to the public, and the remarkable insidious character of its approach makes it highly important that a warning should be given to unprofessional persons in relation to it.

That Bright's disease is curable in its early stage is beyond doubt, and that it is absolutely incurable in its last stage is also beyond doubt; therefore, in order to give an individual suffering with this disease all the advantages of medicine, and as there are no ordinary symptoms by which the disease may be detected, the patient should be as early as possible brought under medical treatment. In the absence of an early medical treatment, the chances of a cure are seriously diminished; for when the structure of an organ of the body is once seriously injured by disease, medical art possesses no means whereby it can be restored to its natural vigor. Let it be distinctly understood that in the early stage of Bright's disease there are no symptoms to denote its presence to the unassisted senses; and in order to detect it, chemistry and the microscope are the only reliable resources for an accurate knowledge of the existence of the presence of the disease.

HOW TO SUSPECT THE DISEASE.

Notwithstanding the constitutional symptoms of chronic Bright's disease are commonly those belonging to any other serious

disease of the important organs of the body, it *has* certain general bodily signs which, when present, may lead the patient to suspect that there is impairment going on in the kidneys.

There are many diseases which make known their presence by the signs which they present; but it is not so with chronic Bright's disease. Its presence must be suspected and looked for, before it can be designated; and in order to attain this end, it must be searched out from among the multitude of common symptoms that accompany it. This is highly important to the patient; for when the disease is once established, it runs to a fatal termination in six months. As a rule, the tendency of the disease is always towards death; but now and then exceptions do occur, where the patient lives a year or two, and sometimes gets well; but this is far from being the rule.

Chronic Bright's disease is not only a disease of the kidneys, but an evidence of a weak constitution and impaired general health; and when an individual suffers month after month from an impaired appetite, with more or less emaciation, accompanied by a gradual loss of energy and unusual fatigue after bodily exertion, with imperfect perspiration and a tendency to rheumatic pains, a peculiar pale and sallow complexion, with a dry or moist and pallid tongue, attended with a dry and harsh state of the skin, headache, drowsiness, and dimness of vision, accompanied with a watery condition of the eyes, associated with dropsical symptoms about the feet and face, he may reasonably suspect that he is suffering from disease of the kidneys, and should lose no time in having his urine chemically and microscopically examined, and in placing himself under the medical treatment of an intelligent physician.

Pathological anatomy tells us all about the morbid condition of the kidney after Bright's disease has destroyed the life of the patient, but possesses no light to fall upon the *dead* organ and throw back rays to indicate means to relieve the *live* kidney struggling with the disease; and science has not yet presented a treatment that even approximates the removal of that depraved condition of the system that silently starts organic changes in the structure of the kidney; and through darkness and doubt we have to grope, and clutch at such means as seem most likely to help the suffering patient. That albumen does now and then make its appearance in the urine without the presence of serious organic disease of the kidneys is doubtless true, but when it occurs continuously, for weeks together in the urine, there can be no question that its continued presence indicates organic disease of the kidneys; and when a physician has a case of Bright's disease under his care, he should tell the patient at once of his condition, and tell him also that no course of medicine will be of any avail whatever, unless assisted on his part by the most perfect temperance and prudence in every act relative to the care of his mental and physical condition.

J. B. Johnson, M. D.

Washington City, D. C.

A Card from Dr. Packard.

In your issue of March 13, the reporter of a clinical lecture of mine at the Pennsylvania Hospital has somewhat mixed up two very different matters, and I beg you will allow me enough of your valuable space to remedy the confusion, which is in the first section, headed "New Method of Applying Extension and Counter-extension."

Your reporter first describes (not very clearly or accurately) the ordinary method in use in fractures of the femur. He next, and as if in contrast with that, gives my plan for making extension in such cases of fracture of the *leg* as may require it. This plan is by no means new, for I published it in *Hays' Journal* for April, 1874, and again in my article on Fractures in vol. iv. of *Ashhurst's Cyclopædia of Surgery*. Your reporter then recurs to fractures of the femur, but it seems to me scarcely does justice to the demonstration I made before the class. My method of making extension is as follows: I take a strip of adhesive plaster, 2½ or 3 inches wide, and about 18 inches longer than twice the distance from the sole of the foot to the seat of fracture. Splitting this strip from either end nearly to the mid-point, I place a bit of thin board, as wide as the strip and about 3 inches long, at the middle of the strip on its adhesive side. Now, it will be easily seen that by placing this bit of wood close below the sole of the foot, one split portion of the plaster will correspond to the outer, the other to the inner side of the limb, and each will have two long ends. These ends are now successively heated and applied to the limb, one portion of each passing in front of the ankle, and the other behind it, thence spirally round the calf, over the swell below the knee, then over the swell above it, and so up to the seat of fracture. In this way four strips of adhesive plaster are made to wind spirally round the limb, fitting very

accurately, and giving a very firm and equable hold upon all that portion of it below the seat of injury to the bone.

This mode of applying extending force is, I *think*, new, but it may be that it has been used by others unknown to me. It was for this only that I made any claim of novelty.

Pray allow me to correct another error, which crept into your report of a lecture of mine, published in your issue of April 3. In the case of railroad injury requiring amputation of the arm, the account reads: "The bone escaped injury, but not so the brachial artery, which was felt distinctly pulsating at the wrist." It should have been: "The bone escaped injury, but not so the brachial artery; this could be felt beating strongly down to a certain point in the wound at the elbow. The pulse at the wrist, however, was not extinct, and it was hoped that the collateral circulation might be sufficient to preserve life in the forearm and hand. As a measure of safety it was deemed necessary to ligate the vessel in the wound."

Trusting I have not presumed too much upon your patience and that of your many readers, I am,

JOHN H. PACKARD, M. D.

1437 *Spruce St., May* 8, 1886.

NEWS AND MISCELLANY.

American Laryngological Association.

The eighth annual Congress of this Association was held in the hall of the College of Physicians in this city, May 27th, 28th, and 29th. The following papers were read:

"Two Instances of Adenoid Disease of the Roof of the Pharynx which exhibited Unusual Features," by Harrison Allen, M. D., of Philadelphia.

"The Intrinsic Muscles of the Larynx," by Prof. Joseph Leidy, M. D., LL. D., of Philadelphia.

"Concerning the Positions of Paralyzed Vocal Bands," by Franklin H. Hooper, M. D., of Boston.

"Laryngeal Vertigo," by Frederick I. Knight, M. D., of Boston.

"Observations on the Use of Some of the Newer Remedies in the Diseases of the Upper Air Passages," by E. L. Shurly, M. D., of Detroit.

"The Simplest and Most Efficient Treatment of Diphtheria," by Wm. H. Daly, M. D., of Pittsburgh.

"The Question of Hemorrhage after Uvulotomy," by E. Carroll Morgan, M. D., of Washington, D. C.

"Further History of the case of Paralysis of the Posterior Crico-Arytenoid Muscles presented at the first meeting of the Association (1879), with report of Autopsy and Exhibition of Specimens," by J. Solis-Cohen, M. D., of Philadelphia.

"A case of Congenital Defect of the Epiglottis, illustrating its Function in Deglutition," by Frank Donaldson, M. D., of Baltimore.

"Buccal Tuberculosis," by D. Bryson Delavan, M. D., of New York.

a "Three cases of Thyrotomy; Recovery in each case case with Excellent Voice."

b "Alarming Hemorrhage after Tonsillar Excision Arrested by Torsion of the Artery," by Clinton Wagner, M. D., of New York.

"The Laryngeal Image as seen in Photographs taken during the production of Tones in the Singing Voice, with Lantern Exhibition of Photographs," by Thomas R. French, M. D., of Brooklyn.

"Clinical Notes on Prolapse of the Laryngeal Ventricles, with cases," by George W. Major, M. D., of Montreal.

"A Novel Procedure for the Removal of Sub-glottic Laryngeal Growths," by Wm. C. Jarvis, M. D., of New York.

"Cases of Laryngeal Œdema," by T. Amory De Blois, M. D., of Boston.

"A case of Perichondritis of the Larynx, with Specimen," by Charles H. Knight, M. D., of New York.

"A case of Gummatous Disease of the Larynx, with Spontaneous Re-opening of Larynx after Thyroid Laryngotomy," by Edgar Holden, M. D., of Newark.

"Gummatous Infiltration at the Base of the Tongue," by U. G. Hitchcock, M. D., of New York.

"A case of Hysterical Sneezing, Apparently Cured by applications to the Nasal Passages of the continuous Battery Current," by S. Solis-Cohen, M. D., of Philadelphia.

"A Contribution to the Pathology and Treatment of the Respiratory Vaso-Motor Neuroses," by John N. Mackenzie, M. D., of Baltimore.

"Inflammation of the Antrum," by Beverly Robinson, M. D., of New York.

"A case of Naso-Pharyngeal Growth," by Samuel Johnston, M. D., of Baltimore.

"What cases of Nasal Catarrh require Surgical Treatment?" by Clarence C. Rice, M. D., of New York.

The annual dinner was given at the Saint George Hotel.

OFFICERS FOR THE ENSUING YEAR.

President—E. F. Ingalls, M. D., Chicago.

First Vice-President—E. C. Morgan, M. D., Washington.

Second Vice-President—J. N. Mackenzie, M. D., Baltimore.

Secretary and Treasurer—D. Bryson Delavan, M. D., New York.

Librarian—Thomas R. French, M. D., Brooklyn.

Drs. Delavan and French were re-elected, but the others are new men. The idea of an excursion was abandoned. The meeting next year will be held in New York.

The Preparation of Wheat Flour.

Any reform which aims at improving the quality of bread must be of general and professional interest. Late years have seen considerable changes in this direction. They have witnessed the reduction to something like its true place in public esteem of mere color as a test of nutritive value. People think less of the white loaf than of yore; it is not now the unique model of perfection in bakery that it was once too readily taken to be. There is more respect for its brown wheaten fellow; and while we are not prepared to admit without reserve all the excellencies which have been claimed for the latter, we may fairly allow that it deserves to rank as a food of highly nutritive efficacy. The principle which preserves in the bran, with its nitrogenous, fatty, and saline constituents, some of the best constituents of wheat, is on the whole a sound one. Its one objection is the inseparable association of irritating silicious matter, which often precludes its free use among the sick, and in any case requires that the grain should be ground with more than usual care. This fact also places somewhat of a restraint upon the consumption of such bread even by the healthy. Among various methods which have been devised in order to meet this difficulty, our readers will recall that of Mège-Mouriès, which, by preserving the inner envelope while removing the outer coverings of the grain, succeeded in retaining most of what was nutritious in the bran with comparatively little indigestible or irritant matter. A revival of this mode of preparation has lately been described by Mrs. K. J. Dance in a little paper on bread-making. The authoress claims for her system that it is both more efficient and more expeditious than other processes now in use. Respecting its proper place among such we need not now express an opinion, but the soundness of the theory on which it is based at all events justifies the claim put forward that it should be fairly tested as to its practical value.

Association of American Physicians.

Below we give the programme of the first annual meeting of this Association, to be held in Washington, June 17 and 18:

THURSDAY, JUNE 17, 10 A. M.

1. Organization. Address by the President, Francis Delafield, M. D., New York.

2. Knee-jerk and Muscle-jerk in Disease, by S. Weir Mitchell, M. D., in conjunction wirh Morris J. Lewes, M. D., Philadelphia.

3. Typhoid Fever, by F. Peyre Porcher, M. D., Charleston, S. C.

Afternoon Session, 3 p. m.

4. Spasm of the Larynx in Rickets, by J. T. Whittaker, M. D., Cincinnati, O.

5. Discussion.—Does the Present State of Knowledge justify a Clinical and Pathological Correlation of Rheumatism, Gout, Diabetes, and Chronic Bright's Disease? Referee, James Tyson, M. D., Philadelphia; Co-referee, W. H. Draper, M. D., New York.

6. Notes on some cases of Diaphragmatic Pleurisy, by E. T. Bruen, M. D., Philadelphia.

FRIDAY, JUNE 18, 10 A. M.

7. Certain Elements found in the Blood of Malarial Fever, by W. T. Councilman, M. D., Baltimore.

8. Certain Clinical Facts Connected with Tabes Dorsalis, by H. N. Lyman, M. D., Chicago.

9. Diseases of the Appendix Cæci, by Reginald H. Fitz, M. D., Boston.

Afternoon Session, 3 p. m.

10. Peri-Uterine Inflammation, by Wm. M. Polk, M. D., New York.

11. An Experimental Study of Glomerulo Nephritis, by W. H. Welch, M. D., Johns Hopkins University, Baltimore.

12. Bicuspid Condition of the Semilunar Valves, by William Osler, M. D., Philadelphia.

Other papers are promised.

Policing the High Seas.

In pursuance of the resolution of the President, who has determined to establish, by means of vessels of the Revenue Marine, a national patrol of the Coast of the United States, so far as it may be practicable under existing law and consistent with the performance of the other duties confided to that service, Captain E. Gabrielson has assumed command of the revenue cutter Hamilton, stationed at this port, and the vessel has proceeded to sea under special orders for the performance of police duty upon her cruis-

ing stations, the limits of which are from Cape Hatteras to Great Egg Harbor Bay. The orders from the Treasury Department require that all in-bound foreign vessels shall be compelled to show clean bills of health before being permitted to proceed up the Delaware Bay and River. In case any sickness is found on board the vessel, or if there have been cases of any contagious disease during the voyage, the craft will be sent to quarantine at the Breakwater. Every effort is to be made to prevent the introduction of cholera into this country, and the Hamilton will continue her patrol during the entire summer.

Quarantine officers will be recognized as follows, viz.: Medical officers or acting assistant surgeons of the Marine Hospital Service in charge of Gulf, South Atlantic, Cape Charles, or Delaware Breakwater quarantines, or any officer of said Service on duty at any port on the interior rivers, the Great Lakes, or Pacific coast, and all quarantine officers acting under proper State or local authority. Special regulations to aid local quarantime authorities will be promulgated hereafter should occasion require.

Food Preservatives.

An interesting paper was recently read by Messrs. Sulman and Berry before the Chemical and Physical Society of University College (London); it was important also from its practical bearing on the preservation of foods, and especially milk. Their investigation, limited to the boracic, salicylic, and benzoic compounds, proved that such substances as aseptin, glacialine, and boroglyceride owed their preservative qualities almost exclusively to the free acid contained in them. Boroglyceride contained 25 per cent. of the genuine boracic ether of glycerine, and 75 per cent. of free acid and glycerine in equivalent proportions. The true compound, the ice-like solid, is immediately resolved into free acid and glycerine by the addition of water, and this reaction probably takes place when the true compound comes into contact with aqueous liquid or animal tissue. We agree with the authors of the paper that the use of so much free boracic acid is undesirable and injurious, especially as a preservative of milk for children. Salicylic acid and salicylates are not substances that can be used with impunity, and as they appear to be useless as preservative agents, their rejection is doubly necessary. Again, benzoic acid precipitates the casein of milk. The best agent appears to be benzoate of soda, which is tasteless when pure, is one-third more powerful than boracic acid, and innocuous when taken in small quantities for prolonged periods.

The Cholera in Italy.

The news from Italy shows that cholera maintains itself steadily in the city of Venice and at Bari. In the seven days ending May 18th there had been 28 deaths from cholera in Venice, but the number of attacks was set down at only 37, which must necessarily be below the mark. At Bari 79 cases and 32 deaths are reported to have taken place during the same period. In the province of Brindisi the attacks, which never exceeded some five a day, gradually fell to a single one on the 14th inst., and since then no fresh attacks have occurred. There has thus been no increase of cholera in Venice and Bari, and elsewhere the disease has abated. This is, so far, satisfactory. But in view of the early season of the year, it would be very premature to attach too much importance to any apparent diminution in the extent of the epidemic. Last year cholera prevailed off and on for several months in the Spanish provence of Valencia before the sudden outburst early in June, which formed the commencement of a widespread epidemic throughout the peninsula. The failure of the disease to make rapid headway in Italy, whether it is owing to meteorological or other conditions, is, however, favorable to the carrying out of such sanitary measures as are known to hinder the spread of cholera; and in such action the best hopes for Italy now lie.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE THREE WEEKS ENDED MAY 22, 1886.

Bailhache, P. H., Surgeon. Detailed as chairman Board for physical examination of candidates for appointment as cadets, Revenue Marine Service, May 19, 1886.

Wyman, Walter, surgeon. Granted leave of absence for thirty days, May 14, 1886.

Stoner, G. W., surgeon. Detailed as recorder, Board for physical examination of candidates for appointment as cadets, Revenue Marine Service, May 19, 1886.

Banks, C. E., passed assistant surgeon. Leave of absence extended four days, May 5, 1886.

Bratton, W. D., assistant surgeon. Detailed as medical officer revenue steamer "Corwin" during cruise, May 22, 1886.

Perry, T. B., assistant surgeon. Appointed an assistant surgeon, May 21, 1886. Assigned to temporary duty at San Francisco, California, May 22, 1886.

Medicines for Internal and External Use.

By a notice recently issued in the District of Potsdam in Prussia, it is ordered that the directions to be affixed to medicines for internal use shall be written on white paper, and to those for external use on bright red paper, on which writing with black ink is easily legible. The latter must also be distinctly marked "external." An order regulating the color of the paper to be used has existed since 1825, but its provisions have gradually been transgressed; hence the new regulations. Such regulations as that to which allusion is now made, are scarcely calculated to obviate the danger of mishap. Difference in the color of paper is useful, so far as it goes; but it appeals to the sense of sight alone; and, as we have already urged, it should be substituted or supplemented by an appeal to the sense of touch, by a difference in the configuration of the bottles used respectively for "internal" and "external" medicaments.

Cholera at Gibraltar in 1885.

The health officer of Gibraltar, Surgeon-Major F. P. Staples, has addressed to the Sanitary Commissioners of that place an interesting report on the cases of cholera which occurred on the Rock in the course of last autumn. Inasmuch as the cases numbered only 34 in all, and the largest number in any one day was two, their occurrence can hardly be described as an epidemic; but it is nevertheless important that as detailed particulars as possible should be placed on record concerning them. This, Surgeon-Major Staples has been at great pains to accomplish in the report before us. He has nothing specially novel to record as to the exciting causes or behavior of the disease, which seems to have been found, as usual, in association with dirt, overcrowding, and general unsanitary conditions.

Lehigh Valley Medical Association.

The sixth annual meeting of this society will be held at the Glen Summit Hotel, Glen Summit, Pa., on Wednesday, June 16.

Glen Summit is a station on the main line of the Lehigh Valley Railroad. The Belvidere Delaware connects with it at Lehigh Junction, just below Phillipsburg. The Central Railroad of New Jersey at Phillipsburg. The Morris & Essex at Easton. At Bethlehem connection is made with the North Pennsylvania and Lehigh and Lackawanna, and at East Penn Junction with the East Pennsylvania Railroad. For the members and guests in Carbon and Luzerne counties, it is not necessary to give traveling directions. Those beyond Wilkes-Barre can take the Lehigh Valley trains at Wilkes-Barre.

For particulars address the President, S. W. Trimmer, M. D., White Haven. Pa.

Epidemic Cholera.

As the warm season advances in the south of Europe, indications of the spread of cholera are again attracting attention. A despatch dated Paris, April 16th, states that sixty-eight cases had occurred in Brindisi, Italy, and that sixteen deaths had taken place between the 8th and the 16th inst. It is reported that very stringent precautions are being taken to prevent its crossing the frontiers of both France and Austria. Still, the officials of Brindisi claim that the disease is sporadic.

New York State Medical Association—Fifth District Branch.

The fourth special meeting of the Fifth District Branch will be held in Kingston, on Tuesday, June 15, 1886. All Fellows are cordially invited to contribute to the meeting, either by reading papers, notes or communications, or by exhibiting specimens. The Secretary will be glad to receive the title of any proposed paper as early as convenient. E. H. Squibb, M. D., *Sec'y.*
P. O. Box 94, Brooklyn, N. Y.

Items.

—The French government has passed a law permitting persons to give their bodies, by will, to learned societies.

—The bill separating the Massachusetts State Board of Health from the State Board of Lunacy and Charity has become a law.

—Prof. Brinton teaches that the only effectual treatment of *anal fissure* is forcible dilatation of the sphincter ani, done thoroughly.

—The curette and a caustic are the best things for lupus, according to Unna. The fashionable caustics are pyrogallic acid and ichthyol.

—Why were the Newark children who were inoculated against hydrophobia, like

Nebuchadnezzar? Ans.—Because they were sent to *Pasteur*.

—An English physician says he has met with no case of offensive urine (intestinal-vesical fistula excepted) that ten or twenty grains of boric acid, given every three hours, would not cure.

—Dr. Edward Fournié, the distinguished laryngologist and aurist, and for a long time Director of the National Asylum for the Deaf and Dumb of France, and editor of the *Revue Médicale*, died on March 24, aged fifty-three years.

—An Italian Surgical Congress has just been successfully held at Rome. Among the contributions was one by Professor Ceci, recounting the history of a successful splenectomy in which the spleen was one-fifteenth of the body weight.

—It is announced that Dr. A. L. Gihon, U. S. N., has been appointed President of the Section of Collective Investigation of the International Medical Congress, in the place of Dr. H. O. Marcy, of Boston, who has been made Vice-president of the Section of Gynecology.

—The Russian Government has issued an order that the practice of massage is only to be allowed to be conducted by those who have obtained a license after examination in the same way as those who practice medical gymnastics are licensed, and the massage must always be carried on under the orders and supervision of a medical man.

—The Secretary of the State Board of Health of New York reported at the recent meeting of the Board, with regard to the results of vaccination throughout the State to ward off the threatened invasion of small-pox from Canada, that the recent experience is a certain preventive of small-pox.

—F. A. Monckton (*Australasian Med. Gaz.*) reports he has cured one case of diabetes mellitus with boric acid. The patient was not stringently dieted, but was given seven grains of the acid three times a day, and at the end of ten weeks the sugar had all disappeared from the urine, the specific gravity being reduced from 1025 to 1016. The drug produces no unpleasant effect.

—Louis Xavier Ollier, the famous French surgeon and medical author, died recently, at the age of sixty-one. He was for many years Professor of Chemical Surgery at the Faculty of Medicine and Pharmacy at Lyons, where he began his famous studies of the bone. He contributed articles to medical periodicals, some of which have been put into book form. Ollier was an officer of the Legion of Honor.

—The Clinical History of King Alfonso, of Spain, has recently been published by his physician, Dr. Tomâs Santero, of Moreno. He regarded the anxiety and excitement aroused by the dispute with Germany over the Caroline Islands as the remote cause of the final outbreak of miliary tuberculosis which led to the king's death.

—A man known as "the Sussex giant" died suddenly at Appleboro, Eng., recently. Although only thirty-six years of age, he weighed over 546 pounds. He was on an exhibition tour, and in one of the intervals between the performances he fell asleep in his chair, and when an attempt was made to arouse him he was found to be dead. The cause of death was heart disease.

OBITUARY NOTICES.

William Owen Baldwin, M. D.

Advices from Montgomery, Alabama, report the death in that city on May 30 of Dr. W. O. Baldwin. Dr. Baldwin was born in Montgomery, August 9, 1818, his mother being a sister of one of the earlier governors of Alabama. He graduated in medicine from Transylvania University, Lexington, Ky., before he was nineteen years of age, when he settled in practice in his native city. He was a member of many medical societies, a liberal contributor to medical literature, and besides having been President of his State Medical Society, he was, in 1869, President of the American Medical Association.

QUERIES AND REPLIES.

A Per Cent. Solution.

Will you please state, under "Queries and Replies," what the component parts of a—say 4—per cent. solution are? My idea is, 96 grains of water and 4 of the drug used. We have had some diffence of opinion here as to how various per cent. solutions are made, and would therefore be glad to have your solution to the problem. S. N. M.

Ans.—Your idea is correct.

Eds. Med. and Surg. Reporter.

Pruritus and Sweating Hands.

In your journal of the 3d inst. is a query for the cure of pruritus. I am troubled occasionally, perhaps two or three times a year, when about to retire for the night, with an intense itching about four inches below Poupart's ligament, which always disappears after one, two, or three applications of tinct. nitrosi, and citron ointment, and immediately before lying down, rubbing with the forefinger a minute or so.

Now, I would like to know a remedy for sweating hands. I have a patient (female) near twelve years old, from whose hands the perspiration will run like water off her fingers when she attempts to sew or use her hands for anything especially. It has always been so.

Edw. Vanderpoel, M. D.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*

2d. *All materials weighed with scrupulous exactness.*

3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*

4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

GREEN SPRING SANITARIUM,

AND

WATER CURE.

For the treatment of all forms of Nervous Diseases, including the Alcohol and Opium habit; also diseases incident to Women, Rheumatism, Skin Diseases and Dyspepsia. Seventy miles west of Cleveland, in a natural grove of ten acres. Sixteen years successful operation. Means and appliances complete. Treatment by baths, electricity and massage, a specialty. One of the largest medicinal springs in America. Elegant apartments. Moderate terms. For particulars address **JOHN S. MARSHALL, M. D., Superintendent, Green Spring, Ohio.**

TAMAR INDIEN GRILLON.

A laxative, refreshing, and medicated Fruit Lozenge, very agreeable to take, and never causing irritation. Its physiological action assures the immediate relief and effectual cure of

CONSTIPATION,

HÆMORRHOIDS, BILE,
CEREBRAL CONGESTION, HEADACHE,
LOSS OF APPETITE,
INTESTINAL OBSTRUCTIONS, ETC.,

by augmenting the peristaltic movement of the intestine without producing undue secretion of the liquids. Unlike pills and the usual purgatives, it does not predispose to intestinal sluggishness, and the same dose always produces the same effect, that is to say, never needs increasing.

It is recommended by the most eminent physicians of Paris, notably Drs. BELIN and TARDIEU, who prescribe it constantly for the above complaints, and with most marked success.

DIRECTIONS TO PARENTS OF DEAF CHILDREN FOR THEIR TREATMENT FROM INFANCY, IN ORDER THAT THEY MAY LEARN SPEECH AND LIP-READING.*

BY MISS MARY S. GARRETT,
Of Philadelphia,
Principal of School for Teaching Deaf Children to Speak.

All deaf children whose eyesight is good and who are not idiotic, can, with extremely rare exceptions, be taught to talk and can learn lip-reading, provided their parents, care-takers and teachers know how to guide and teach them. When parents discover an infant to be deaf, they should continue to talk to it, just as every mother does to a hearing baby when it is learning to talk; she does not use motions to it, because it has not yet commenced to understand her language, but she repeats over and over again to it the pet names she calls it, tells it again and again to "say papa," "say mamma," etc., etc., until it learns to understand and then to copy her words. She is keen to discover, encourage, and correct its first attempts at articulation.

The attention of the deaf infant should be directed to the mouth, with the same persistence, and it should be talked to just the same by every one who is with it. No more motions should be used with it, than with a hearing child; its attention should be always guided to the mouth of the speaker and concentrated there. Little by little it will begin to attach meaning to the words and sentences it sees, just as the hearing child little by little learns to attach meaning to the words and sentences that it hears. People almost universally when they wish to take an infant from its mother hold out their arms and say, "Come," watching the little one for an indication in its face of its desire to be taken, or to see if it will hold out its arms to come. Thus the child learns the meaning of the word "come," but as it grows older the parent or others simply call it to come, without holding out the arms, dropping the motion as soon as the child understands the word. No more motions should be used with a deaf child than this, which amounts simply to showing the action represented by a word; the words should be indefinitely repeated, that the child may become familiar with their looks on the mouth, while the representation of an action should be dropped as soon as possible, and should never be made without at the same time showing the child the word representing it. The names of objects may be taught with the objects, which is really the way in which hearing children learn them in their homes. We must always remember that when a hearing child is learning to talk, its hearing gives it the advantage of every word spoken in its presence, while the deaf child only has the advantage of seeing the mouth of the person it happens to be looking at, or who is talking with it, and this difference must be made up to the deaf child, by a great amount of repetition of the words and language we are teaching it.

Every one with whom a deaf child comes in contact should talk to it and encourage and aid it to articulate. Deaf babies begin

* Read before the Medical Society of the State of Pennsylvania.

to say ma-ma-ma just as hearing babies do, but as a rule it is not encouraged in them ; if it were, and the child properly guided to further articulation, it would talk.

Miss Fuller, principal of the Horace Mann School at Boston, quotes in her report for 1885 a part of a letter which she received "from the mother of a congenitally deaf pupil, now seven years of age, who is able to use speech and to understand it upon the lips of others to a remarkable degree." Miss Fuller says further, that the letter "shows what a mother had done before her child entered school at the age of four years."

The mother writes: "In trying to recall what Bertha learned in the first three years of her life, I realize the fact that it was through ignorance of her total deafness that we taught her anything. Thinking all the time, that she was very backward in learning to talk, we took unusual pains with her, saying over the simple words that children catch so easily. If we had known at the beginning that she heard nothing, when we spoke to her, I am afraid instead of teaching her what little we did, we should have been discouraged and used signs. As it was, she had learned to speak many words before she entered school. 'Papa' and 'mamma' were the first words that she learned. We would say, 'Come and see papa,' or 'Come and see mamma,' and at the same time hold out our hands to her. In a short time she learned to recognize us by these names and call us by them. To be sure, the words sounded very much alike when she spoke them, but hearing children often speak imperfectly at first. When she was sitting on the floor, I would say 'Up' to her, and partly lift her, so that she soon learned what the word signified, and would say, 'Mamma, up.' She always lived among uncles and aunts, who have helped us in teaching her to talk. None of them ever used signs with her, but talked as with a hearing child. When quite young she learned to call them by their respective names. If she wanted to go to one of them she was induced to say 'Auntie Jennie,' or 'Uncle George,' before she was gratified. In the same manner she learned to speak the name of any object that interested her. To teach her that she must not play with the stove, I showed her that it soiled her hands, and told her they were 'all black.' If she disobeyed, she would come to me, hold up her hands, and say 'All black.' At one time we lived in a house with a family, to whom Bertha became very much attached. She learned to call them by name, and when we took her to see them, we always asked her if she wanted to go upstairs. It was not long before she would say 'up-stairs' to us, many times in the day, meaning to ask us if she could go up.

In this way we did what we could for her until we took her to school. The manner in which we had begun with her was very kindly commended, and we were advised to continue talking with her and teaching her words, which we have done. None of her questions, and they are very numerous, are ever allowed to go unanswered. We always encourage her to talk to us about her play and everything that interests her, and try to explain what she does not understand. But our feeble efforts seem like nothing in comparison with what her teacher has done and is still doing for her. We appreciate it all, and only hope that Bertha may long remain under her skilful guidance and care."

No one should be allowed to make motions or signs to the child, or to teach it the manual alphabet, as it grows older. It should be strictly trained to depend on lip-reading and that alone. When the child is old enough, it may be taught to write words and sentences as soon as it can articulate them and read them from the lips, but not before.

There are no doubt mothers who would be skilful enough in training their children from the beginning so that they would never need to go to special schools for the deaf, but could be taught with the hearing ; probably, however, the majority of parents would need to send their children to schools taught by specially trained articulation teachers, for awhile at least. Such teachers should be equally strict that all communications with their pupils, in classes and out of classes, at the table, on the play-ground, and on all occasions, should be through speech and speech alone. It is the universal experience that hearing children who study French and German in English schools, where all their lessons, outside of these special classes, are recited in English, do not learn to speak these languages. If deaf children are given special lessons in articulation in schools where they see signs and the manual alphabet used constantly around them, and where they use them in the play-ground, at the table or in their classes, the cases where they become proficient in the actual use of speech and lip-reading will be as rare as of those hearing children who become proficient in French and German under similar circumstances.

Children or grown persons who lose their

hearing through sickness, should at once be trained to read the lips and encouraged to talk just as they did before, and they should as studiously be kept from all contact with signs or manual alphabet as the congenitally deaf.

Miss Emma Garrett, Principal of the Pennsylvania Oral School for the Deaf at Scranton, Pa., describes in the January number of the *Annals of the Deaf* for 1886, the case of a pupil of hers. He was a young lad who lost his hearing in May, 1885. Under her direction he was induced to continue to talk as before and to depend on lip-reading alone for his communication with others; after spending a very few weeks under her instruction in the autumn, he was able to take his place in the hearing school which he had formerly attended, and all his communication there is through speech and lip-reading. There is a great difference in the aptitude of this class of the deaf for acquiring lip-reading; some seem to be what might be called natural lip-readers, and learn it from their associates simply by watching their lips, while others need training from special teachers. All such persons should, however, train themselves or be trained to depend on lip-reading and speech, and not on writing.

It needs very little reflection on the part of intelligent minds to estimate the difference in the life of a person who is able to understand the speech of those around him, and to make himself understood by them, from the life of one who knows only signs and the manual alphabet, which are almost unknown outside of the institutions where they are taught.

As there is only one deaf person to every 1500 hearing persons in our population, it behooves us to help that one deaf person to fit himself for communication with those 1500. We cannot expect the 1500 to learn manual alphabets or arbitrary signs to suit the one deaf person.

There is a popular delusion that the vocal organs of deaf children are defective; the fact is, that such cases are rare exceptions, and that as a rule their vocal organs are normal. The articulation of consonant sounds depends on certain positions of the lips, tongue, teeth and palate. The quality of vowel sounds depends on certain positions of the tongue. Any deaf child who can cry, and scream, and has lips, tongue, teeth and palate, has the necessary vocal organs.

The deaf children are capable of being taught by the *Pure Oral Method*, and the method is a success when parents, care-takers and teachers know how to apply it. It is possible for deaf born children to learn speech and lip-reading after they begin to go to school, if they have competent teachers, but much time would be saved and far better results obtained if parents would do their part before the child is sent to school.

Great results have already been gained through the Oral Method, and I have no doubt that greater and better results than any already obtained await us in the future, as the method becomes more widely and more strictly and intelligently applied. The oral pupil who has the least amount of intelligible speech and of lip-reading compared with his fellow oral pupils, has just that much advantage over the most expert maker of arbitrary signs and the manual alphabet, which are sure to be as unintelligible to the general public as our speech is to the sign-maker.

The more perfect we can make the speech of the deaf, and the more skilful we can train them to be in lip-reading, and the greater the amount of language we can teach them, the happier and more independent they will be.

LAPAROTOMY FOR PISTOL-SHOT OF ABDOMEN.

BY J. Mc F. GASTON, M. D.,

Of Atlanta, Ga.

For the history of this case at the outset, the following brief statements of Dr. C. C. Quillan are given:

He was called before daylight, December 26, 1885, to visit W. O., a colored man, about thirty years old, who had been shot at short range with a pistol, but size of ball not known, immediately below the point of last rib, on the left side, and found the patient in a very prostrate condition. He was almost pulseless, with consciousness very much impaired, which was attributed to shock. It was with difficulty that he was induced to take the alcoholic stimulants which seemed to be indicated, and it was found only after five or six hours of persevering efforts that he rallied. He was subsequently given morphine to allay his sufferings upon reaction.

An examination showed little change from the normal temperature—tympanitis manifested itself early that day.

The treatment during the two following days was confined to spirits, with a view to composure, and the prevention of the peristaltic action of the bowels, in anticipation of peritonitis by him and Dr. W. B. Parks, in consultation.

Nothing could be learned from the relative position of the offending and the offended party as to the probable course of the ball, but it was inferred that it had penetrated the peritoneal cavity. Noting great increase of the abdominal distension, with sensitiveness on pressure, enemata were given on the third and fourth days without effect.

The temperature in the mean time had gradually increased from 101° on the second day up to 103° Fahrenheit on the fourth day, with thirst and great distress from the distention of the abdomen pressing up against the diaphragm. The tension seemed to threaten disruption of the parietal integument.

Four days had elapsed after the receipt of injury by the pistol ball when my attention was called to the patient, and the indications of peritoneal inflammation, by local as well as constitutional symptoms, made the prognosis of the gravest order; yet in consideration of a certain fatal termination without laparotomy, it was thought expedient to perform this operation as a dernier resort, after an exploratory puncture of the walls.

Upon completing the incision in the linea alba, with a deviation at the umbilicus, the distended intestines protruded; and the arch of the colon, being most salient, was punctured with the same trocar which had been used for the preliminary puncture in the parietal wall. There was a free discharge of gas, leading to collapse of the large intestine, but without any diminution of the distention of the small intestines. The ileo-cæcal attachment being sought with the fingers, they were carried along the ileum until several feet of this canal were brought outside of the abdominal walls and protected by cloths wrung out of warm carbolized water, when a puncture was made through its walls, leaving only this portion of the intestine exposed, while gentle pressure was made through the wrapping, to expel the gas from the protruded coils, which intervened between the opening and the ileo-cæcal attachment.

The prospect seemed favorable thus far in employing the canula of the trocar, for the escape of the gas in the first instance, and subsequently of fluid accumulation. Again, I proceeded to draw out another portion of the intestine, keeping this, as the previous part, covered with the cloths soaked with warm carbolized water, and finding still great distention, another puncture was made for its relief. Thus the several segments were dealt with until six punctures had been made in the course of the small intestines; and yet there remained in some portions of the canal considerable gaseous distention, owing to the angular folds of the bowel, which precluded its passage, even under pressure, from the openings in the intestinal walls.

Each of these orifices was closed by two crucial stitches of catgut suture, so as to obviate the escape of fluid contents into the peritoneal cavity subsequently; and this mode of procedure seemed preferable to incisions, which have been recommended, as the number of such incisions that would have been requisite must have necessitated delay in suturing them, which should be obviated so far as possible when the cavity of the abdomen is exposed, as in this case.

Moreover, there is no trouble from hemorrhage in making the puncture with the trocar, and by the use of the canula all the fluid discharge is more effectually carried away from the peritoneal cavity. Having traversed the entire tract of the small intestines without discovering any perforation from the ball, this mass was kept covered with the moist warm carbolized wrappings outside of the abdominal walls, while a close examination of the colon was undertaken by the touch and by sight so far as was practicable with the light of a kerosene lamp held by an assistant. Commencing again at the ileo-cæcal connection, no lesion was discovered until the secondary colon was reached, where a recently-formed band of plastic matter bound the walls of the large intestine to the parietal wall on the left side, immediately over the position of their natural attachment outside the peritoneum. This deposit was sufficiently firm to arrest completely the progress of the contents, and to prevent the passage of even the gaseous accumulation that had occurred above it, but offered little resistance to very slight force with the fingers, so that it was torn loose and the lumen of the colon was restored. Upon searching for the inner orifice of the ball in its passage through the parietes, it was found on a careful palpation of the peritoneal lining membrane to indicate a somewhat oblique direction downward from the opening made in the integument, which was already agglutinated, as no suppuration ensued.

Upon comparing the course taken with the site of these orifices in line with the exudation, there was evidence of abrasion of the outer coating of the wall of the colon at this point, but without penetrating its cavity. There had not occurred any perforation of the walls of either the small or large intes-

tines, and yet hemorrhage had ensued, so as to leave a considerable sanguineous collection within the abdominal cavity that had undergone decomposition. The extension of inflammation from the local injury to the parietal membrane was not as serious a feature as the entire obstruction of the large intestine by the plastic lymph, which formed a constricting band at the seat of injury; and yet there was indication of general peritonitis, or at least engorgement of the serous membrane throughout the cavity, and in its reflexions over the intestines.

The failure to give exit for the gas, accumulated in the several sections of the small intestines, by six different openings in various portions of the canal, can be explained by the closure of its lumen from the angular folding of the walls induced by the distention with gaseous contents. It would have seemed a natural result, that all the gas collected anywhere in the vicinity of such an opening should have escaped through the canula of the trocar with gentle manipulations; but there still remained considerable distension in each coil of intestine. The colon, not admitting of such reduplication of its walls, was completely emptied above the constriction by a single opening with the trocar; and yet the accumulation beyond the ileo-cæcal valve did not find its way out, so that a large tube reaching up into the sigmoid flexure, or even to the arch of the colon, cannot be relied on to remove gas from the small intestines. This does not result from any impediment at the ileo-cæcal connection, as there existed nothing there to prevent the forward expulsion of the flatus, but it is caused undoubtedly by the doubling of the canal upon itself at sharp angles from the great distention. If an ordinary flexible rubber tube be bent upon itself at an acute angle, it will obstruct its lumen so that neither fluid or gas can pass through it; and in the same manner the arrest occurred in this case from the angular flexure of the intestinal tube.

While the coils of the small intestine lay outside of the abdomen, the cavity was relieved of the decomposed sanguineous deposits by sponges wrung out of warm carbolized water; as this was a more expeditious mode of proceeding, and was greatly facilitated by the open space in the absence of the bowels from the cavity, it was adopted, with a full conviction of the greater benefits of thorough washing over mopping out impurities.

Less time was consumed with sponges for the purpose of cleansing the interior surfaces than by the flooding process, which is preferable under ordinary circumstances for making the toilet of the peritoneal cavity, and which I have inculcated in reporting a case of laparotomy elsewhere. This being accomplished satisfactorily, the bowels were returned by commencing at the duodenum and gradually passing in the coils of intestine, some of which were still so much distended as to present considerable difficulty in getting them all within the parietes; but as the obstruction below was now removed, it was expected that the diffusion of the local accumulation would afford relief to the entire tract of the canal.

To save time, that seemed a matter of paramount importance in the extremely prostrate condition of the patient, the iron-dyed silk sutures were passed through the entire thickness of the parietes, including the peritoneal lining, and thus the abdominal wound was closed, leaving only space for the drainage-tube at the lower angle. The patient rallied from the chloroform, but notwithstanding the subcutaneous use of brandy, he succumbed shortly afterwards. The autopsy on the following day by the county physician verified the observation that no perforation of the intestine was made by the ball, yet it was not found upon exploration of the abdominal cavity.

In my article upon "Obscure Impediments of the Intestinal Canal," in the December number of *Gaillard's Journal*, a case of gun-shot wound of the abdomen is reported, in which a very similar obstruction of the descending colon occurred; this obstruction was accompanied with an ulceration of the coats of the canal about their agglutination to the parietes, leading to extravasation of fæcal matter into the cellular tissue, and a cloaca extending downward along the margin of the quadratus. Fluctuation being perceived through the integument, an exploring needle detected a fluid fæcal collection. But the true source of this accumulation was not discovered until the autopsy proved its origin to be from the ulcerated communication with the left curvature of the arch of the colon.

In that case, as well as the one now reported, it was found impracticable to force any considerable portion of the enemata into the bowels, owing to the regurgitation of the fluid by the side of the injection pipe, and it was inferred that some obstacle to their passage existed. An exploration of the colon with the hand in each of these cases would perhaps have enabled me to open up the communication between the up-

per and lower portions of the large intestine. My preconceived objections, founded upon unfortunate results of this proceeding in the experience of others, would not prevent me, nor should they deter others, from undertaking this measure of relief in similar cases, when the large elastic tube fails to overcome the impediment.

CIRCUMSCRIBED PERITONEAL DROPSY SIMULATING OVARIAN DROPSY.

BY H. P. C. WILSON, M. D.,

Of Baltimore, Md.

(*Concluded from page* 711.)

Dr. West, in his work on Diseases of Women, says: "One instance of this latter occurrence has come under my own observation, in which between four and five quarts of a *dark* fluid were collected between folds of the omentum, and during the patient's lifetime frequent discharges of a similar fluid had taken place from the umbilicus. The dropsy had during the life of the patient been supposed to be ovarian; but though malignant disease of both ovaries was discovered, yet neither of them contained fluid at all similar in character to that which was found in the omentum; nor, indeed, could either be detected till after the fluid in the omental cyst had been let out. I am aware of no means by which such cases are to be discriminated from ovarian dropsy. As far as I know, their nature has scarcely ever been suspected during the lifetime of the patient."

Dr. T. Spencer Wells reports a case in which he suspected ovarian dropsy. He carefully opened the abdominal cavity below the umbilicus. No cyst appeared. A large quantity of opalescent fluid escaped. The whole peritoneum was studded with tubercles. Some coils of small intestines were floating, but the great mass was bound down with the colon and omentum, towards the back and upper part of the abdomen. She went through a sharp attack of peritonitis, but recovered, and has been well ever since the operation. No more fluid was secreted, and the patient regained health and strength, and married. The operation was done in 1862, and Mr. Wells reports the woman well in 1881.

I might report many other cases of circumscribed peritoneal dropsy, so simulating ovarian dropsy as to lead to an erroneous diagnosis, which was only rectified by an exploratory incision or a post-mortem examination, but I will not weary you further.

The greater my experience, the more I am impressed with the propriety of such incisions in all cases of abdominal tumors where life is involved. I am convinced that many more lives are lost for the want of such incisions than on account of them.

To Dr. Robert T. Wilson I am indebted for the following history, as well as the treatment of the case subsequent to the operation.

First day, 15th February, 9 p. m.—Temperature 103°, pulse 120, respiration 22. Abdomen distended. All dressings were removed, and the abdomen covered with cloths, wrung out of cold water, to be renewed every few minutes throughout the night. Pulse feeble. Gave 10 drops of tincture digitalis every two hours, and a teaspoonful of very hot water occasionally. At 9:35 p. m. she was given 20 m. of muriate of quinia and urea, hypodermically, and ordered half an ounce of milk every two hours. At 10 p. m. she was becoming restless. and was given 10 m. of Magendie's solution of morphia under the skin.

Second day, 16th February, 7:30 a. m. Temperature $101\frac{4}{5}°$, pulse 100, respiration 20. Had a good night. Took nourishment well. Passed urine and also flatus freely. Had no nausea or pain. Tongue dry. Gave hypodermically 7 m. of Magendie's solution. Digitalis, cold applications to abdomen, and milk continued. A teaspoonful of whisky was added to each portion of milk.

1 p. m.—Temperature $100\frac{3}{4}°$, pulse 92, respiration 20. Tympanitis great, but continues to pass flatus freely. Urinates freely. Bears her milk, whisky, and digitalis well. Treatment continued as before.

4:30 p. m.—Temperature $101\frac{4}{5}°$, pulse 104, respiration 24. Pulse stronger. Tympanitis increased. No unusual tenderness after such an incision. No pain. Is calm and comfortable. At 3:45 vomited for the first time. She attributed it to the whisky, which was always disgusting to her; so it was stopped by the mouth, and ʒij were given per rectum every six hours. ʒj of milk and ʒij of lime water were given by the mouth every two hours. Cold water dressings and digitalis continued as before. Tongue still dry.

Third day, 17th February, 8 a. m.—Temperature 98°, pulse 100, respiration 20. Pulse stronger. She passed a comfortable night. Had no nausea nor vomiting. No pain. Passed urine and flatus. Took nourishment well. All treatment continued as yesterday.

3:45 p. m.—Temperature 98⅕°, pulse 112, respiration 20. Has had two liquid evacuations, passing urine and much flatus at the same time. Stopped whisky enemas, and gave 25 drops of laudanum in an ounce of starch water, ordering the same to be repeated after each evacuation; she required no more. This enema and the two small hypodermics of morphia reported above, is all the opium given in this case. ʒij of sherry wine every three hours, by the mouth, were ordered, as she thought she would relish it; but it was soon discontinued, as it became distasteful. Tympanitis still great. Milk and lime water, digitalis and cold water dressings continued. Tongue more moist.

Fourth day, 18th February, 9:30 a. m.—Sleeping. Pulse 100, respiration 18. Had a good night, and bore her nourishment and medication well.

5 p. m.—Temperature 99°, pulse 100, respiration 20. Has passed much flatus. Abdomen soft, and bears pressure well. Abdominal wound united by first intention. She expresses herself as very comfortable. Treatment continued.

Fifth day, 19th February.—Temperature 98⅘°, pulse 100, respiration 20. Doing well. Tongue moist. Abdomen soft. Taking ʒij of milk every two hours, with lime water. Treatment continued.

Sixth day, 20th February.—Temperature 98⅘°, pulse 100, respiration 20. Doing well, and treatment continued.

Eighth day, 22d February.—Temperature 100⅕°, pulse 100, respiration 20. A small abscess opened along one of the wires, which no doubt sent up her temperature. Abdomen soft and no tenderness. Tongue moist. Appetite ravenous. Wants "middling and greens." She is now allowed all the milk she wants, a soft-boiled egg for breakfast, and good soup for dinner. She had some sweating last night, and was ordered ʒj of infusion of cinchona bark, and 25 drops of aromatic sulphuric acid in it, three times daily. She is bright and cheerful and jokey, and expresses herself as feeling very well. The digitalis was stopped.

Sixteenth day, March 2d.—The patient has had no unpleasant symptom since last report, except the formation of several abscesses along the wires. They united, and caused a superficial gaping of the abdominal incision. This is rapidly closing by granulation. She looks much improved since the operation. Appetite good; sleeps well; bowels regular; is cheerful and bright, and out of all danger.

A SIMPLE REMEDY FOR CHRONIC DIARRHŒA.

BY T. C. SMITH, M. D.,

Of Aurora, Indiana.

A means of cure that is very simple is very liable to be neglected or overlooked, while a remedy with a dignified name and an honorable therapeutic history is chosen instead. We do not offer the remedy we are about to name as one original with us. It was gathered from one of our leading journals a long time ago, and stowed away for future use, if memory should not prove too treacherous to permit its recall. It was first, as far as I remember, suggested by "some old woman" to a physician in Missouri for chronic dysentery. He was wise enough to try it and profit by its use. He found it to surpass his expectations by very far, and finally published it to the world, though I doubt whether the world noted it or cared for it. The remedy was too insignificant to be worthy of remembrance, perhaps, in the minds of a noble, dignified profession that never (?) deals in little things.

Mr. X., an old man, formerly a Mexican soldier, came to me about two years ago for another disease, but incidentally mentioned his chronic diarrhœa, which he said had afflicted him most of the time since he was in the Mexican war nearly forty years ago. Soon after his recovery from the trouble for which he applied to me, I ordered for him a saturated solution of *salt* and *cider vinegar*, of which he was to take a drachm three or four times a day. I had little expectation of benefit for him. However, he returned no more for the remedy. Meeting him some months later, I asked him about his chronic diarrhœa, when he said, "That salt and vinegar has cured me." He did not have it again for eighteen months, when it returned. The remedy was again used, but I do not now know with what result.

Mrs. L. had been the subject of dyspepsia and chronic diarrhœa for about five years, "had suffered much of many physicians," etc. She came under my care about fifteen months ago, during accouchement. Her depraved condition of blood, dyspepsia, and chronic diarrhœa, in connection with the heavy strain of gestation and delivery, caused her to run down so low that her life was despaired of, and at each visit I expected to see crape on the door.

It would take pages to tell the course of treatment pursued by myself first, and after that under advice of counsel. I will omit all that as tedious and needless. Suffice it to

say that at last, and not from any special hope of benefit, I placed her on the salt and vinegar in half-drachm doses every four hours. There was little change for some days, but it was continued. Then she begun to have control of her passages, a little food was digested and retained, and from that time on she improved slowly until recovery was fairly good. Within the last two months there has been a slight return of her old dyspepsia and diarrhœa, but under this simple remedy it has again quite disappeared, and she is gaining flesh.

Other less severe cases could be given where the relief was prompt and seemingly thorough. Whether this remedy will act well in all of this class of cases may be reasonably doubted. Nor do I yet have an unbounded faith in it. A few cases are not enough to establish its merits or fairly test its value. Time will soon discover both of these, for its weal or woe.

I will not insult the intelligence of readers by attempting to give its mode of action. I will only suggest that our common salt is not used as a remedial agent as much as it justly deserves. Like many other valuable agents, it is by far too common; but what is easier than to enclose a dose of salt in a capsule, and give it as we would any other remedy of a dignified name, or we can dignify it, if need be, with its technical designation.

Medical Societies.

BALTIMORE GYNÆCOLOGICAL AND OBSTETRICAL SOCIETY.

Stated meeting held April 13, 1886.

The President, George W. Miltenberger, M. D., in the chair. Wm. E. Moseley, M. D., Secretary.

DISCUSSION ON DR. W. P. CHUNN'S PAPER.

(Read at last meeting.)

Dr. P. F. Mundé said he had operated twice for the removal of uterine fibro-myomas. In the first case he was able to find the second ovary only after complete removal of the tumor. The ovary was adherent deep in Douglas' pouch, and had to be ligated *in situ*. The stump was secured by long pins and constricted by a wire serre-noeud, which came away on the sixteenth day. The second case was diagnosticated to be a semi-solid ovarian cyst, but proved to be a myoma attached to the uterus by a long pedicle. Palpation was obscured by œdema of the fat abdominal walls. The growth was adherent to all surrounding tissues, and in its removal both the mesentery and intestines were unavoidably torn. All rents were immediately sutured. In the after-treatment of the case, a saline solution was transfused into the patient's blood. Secondary hemorrhage ensued, when a second transfusion was resorted to and the wound opened, and bleeding points secured, but, in spite of all, death ensued after 36 hours.

In one case of double ovariotomy, with some adhesions, he had hesitated until the last moment about introducing a drainage-tube, because there seemed to be no oozing whatever, but finally did so, and the next morning he removed some ten ounces of bloody serum through it, which discharge continued several days. He thought œdemalous abdominal walls were not at all common in connection with ovarian cysts.

Dr. W. P. Chunn said he would like to state, in regard to his case, that he considered his patient as now fully recovered. The urinary fistula has entirely closed, the woman is up and about and rapidly gaining strength and flesh. Since the last meeting he has looked up the subject of the action of the adhesions attaching the pedicle to the abdominal walls, and found that his opinion, as expressed in his paper, that the adhesions would, in time, become stretched, so as to allow the remaining portion of the uterus to resume its normal position, was in accord with the views of Dr. T. A. Emmet. Also that the opinion advanced, that by the stretching of the adhesions the fistula would become obliterated, had been verified.

Dr. T. A. Ashley remarked that there was one fact in connection with the case reported by Dr. Chunn which greatly interested him. He had reference to the occurrence of an ovarian tumor in a negro woman. He was convinced that ovarian tumors were of the rarest occurrence in the negro race. He had investigated the literature of ovariotomy very fully, and was surprised to find so few references to this fact. Neither Wells, Keith, nor Tait, have reported ovarian tumors among negro women, but this omission was satisfactorily accounted for on the ground that these operators seldom treated negro women. In the United States, and especially in the southern portion, where a large negro population resided, one would expect to find reports of ovariotomies among these women, unless they were exempted from such pathological conditions by race peculiarities. Dr. Ashley said the only cases he could find in his researches through various authorities were one case reported by Dr. W. L. Atlee,

and the case reported by Dr. Chunn. He had no doubt other cases had been observed by operators, but he had not been able to find records of them. His attention was first called to this subject several years ago by a case which came under his observation through the courtesy of Dr. J. M. Hundley, of this city. The patient was a negro woman, between 40 and 45 years of age, whose abdomen contained a large cystic tumor, which was undoubtedly ovarian in its nature. The physical signs, history, and condition of the patient were those of an ovarian cyst. The only facts which could render the diagnosis doubtful, were the race peculiarity in respect to ovarian cysts, and a failure to corroborate this opinion by an ovariotomy. An operation was urged, but declined by the patient. Subsequently the patient induced another physician to tap the cyst with a trocar, and she died very shortly thereafter. As the case passed from under Dr. Hundley's observation, the name of the physician who performed paracentesis and the complete history of the case were not obtained. Dr. Ashley was satisfied as to the correctness of his diagnosis, and the only doubt which arose in his mind was created by the very rare occurrence of ovarian cysts in the African race. The patient referred to had about one-fourth white blood in her system, which may have some connection with the history of ovarian cyst.

Dr. P. C. Williams read the following paper:

An Unusual Case of Post-partum Hemorrhage.

Strictly speaking, "post-partum hemorrhage" is limited to the puerperal process attending or immediately succeeding the third stage of labor. In that sense, the case I am about briefly to report is incorrectly named, but it is difficult to designate it in other terms, and I have ventured to call it "An unusual case of post-partum hemorrhage." February 1, 1886, Mrs. S., a strong, healthy, well-formed woman, was confined with her first child. The labor presented no complication, and was completed within a reasonable time under the influence of a moderate quantity of chloroform. The placenta was examined and was found to have come away entire, with but very slight loss of blood. There was an abundant flow of milk on the third day. The convalescence progressed perfectly until the fifth day, when I was sent for with great urgency. I was soon at the house, and found the lady flooding violently; the bed filled with blood, and the woman pulseless and prostrated to an alarming degree. The nurse had already given two teaspoonful doses of fluid extract of ergot, and had applied ice freely to the abdomen. Placing my hand on the abdomen, I found it filled with the womb, which was distended to the size of an eighth-month pregnancy.

Recognizing the gravity of the position, I immediately administered, hypodermically, a drachm of fluid extract of ergot. I then inserted my hand and emptied the womb of the clots which had so largely distended it. As soon as it was emptied, I made constant, strong pressure upon the abdomen, and soon found that the ergot began to act, and produce decided contraction of the womb. I then gave another hypodermic dose of ergot, which, with the continued pressure upon the abdomen, *maintained* the uterine contraction, and the hemorrhage was checked and never returned. The woman was frightfully reduced by the great loss of blood which she had experienced, but she soon began to rally, and went on to a steady and complete restoration of health.

I was at great loss to explain the cause of this excessive and unexpected hemorrhage. I had seen my patient at 10 o'clock that morning, when she was apparently perfectly well. At 1 o'clock that night was sent for and found the condition I have described. What could have produced the hemorrhage? The woman was about twenty years old, had always enjoyed uninterrupted health (I had known her since her birth), had had no trouble during her period of pregnancy, her confinement was a little tedious, but perfectly natural; there was very slight loss of blood during the labor, the placenta was expelled *entire*, and the progress of the case was unusually satisfactory until the eighth day, when the sudden change took place that produced the formidable hemorrhage above described. Upon careful inquiry, I finally ascertained, through the lady's husband, that she was in the habit of putting herself to sleep by the inhalation of *chloroform liniment*, with which she saturated a handkerchief and applied it over her nose and mouth. This liniment consisted of two parts tinct. camphor, and one part each of tinct. aconite and chloroform. She had inhaled this liniment night after night for several weeks before her confinement, and had gradually increased the quantity, until she used *eight or ten ounces every night.* The night in question she had used it with unusual freedom, and at 1 o'clock it had affected her so profoundly as to produce this alarming hemorrhage. She was made to

understand the great danger her continuing the inhalation of the liniment and readily consented to abandon its use entirely. For a few nights, I gave hypodermic doses of morphia to secure necessary sleep. The dose of morphia was gradually diminished, and after *ten days* was wholly discontinued. This case interested me greatly.

1. It was the first of the sort that I had ever seen.

2. It proved the great power of the hypodermic use of ergot in controlling uterine hemorrhage. In this case, as in others in which I have used it, its effect was almost instantaneous.

3. It is wonderful that any one could habitually inhale a mixture containing so much aconite, viz., two ounces to the half-pint, and experience so little constitutional injury; as both before and after the hemorrhage referred to, her health has been perfectly good and has so continued until the present time.

Dr. B. B. Browne asked Dr. W. if any remains of placenta or membranes were found in the clots passed by his patient, and cited a case reported by Dr. Coskery before the Clinical Society. In this case, examination of the placenta seemed to show that it had come away entire, but in the inner surface of the uterus, which was removed post-mortem, there was quite a mass of placental tissue. Dr. Browne referred to a case of post-partum hemorrhage which he had recently seen, in which the fld. ext. ergot injected hypodermically seemed to produce rapid contraction of the uterus, but as an intra-uterine injection of equal parts of vinegar and very hot water was used at the same time, it was impossible to tell which was the most active in checking the hemorrhage.

Dr. C. H. Riley said he had seen one case somewhat similar to Dr. Williams'. The patient, a primipara, got along very well for about a week following labor. At this time, to determine the exact position of the uterus, he introduced a sound with great care, but the examination was followed by profuse flooding. He tamponed the vagina, and left the tampon in for two days. There was no return of the hemorrhage.

Dr. G. Lane Taneyhill stated that he had used Bonjeau's preparation of *ergotine* hypodermically with admirable results in cases of post-partum hemorrhage. Thirty grains of the ergotine were dissolved in 450 drops of glycerine, and 20 drops of this solution were injected. It was not necessary to repeat the injection.

Dr. Ashley remarked that whilst the treatment of post-partum hemorrhage was being considered he would say that he had had an experience with vinegar as a hæmostatic in post-partum hemorrhage, which confirmed his opinion in regard to its great value in cases which could not be controlled with ergot and other agents. He then related a case of violent hemorrhage coming on at the time of delivery from an atonic and fagged out uterus. He gave ergot hypodermically twice, injected hot water into the uterus, used pressure and taxis; still the uterine contraction was unsatisfactory, and the loss of blood was kept up. He next called for vinegar; a half-galllon or more was emptied into a basin, and with a Davidson syringe a stream was gently injected into the uterine cavity. Before the basin was emptied, the uterus began to contract firmly. Hemorrhage ceased promptly, and did not return. Dr. Ashley believes that vinegar acts both as a hæmostatic and as an antiseptic. He favored the plan of using the syringe instead of a sponge, as recommended by the late Dr. Penrose. The long tube of the syringe could be carried well into the uterine cavity. There was less danger in this than from the introduction of the hand.

Dr. George W. Miltenberger said that Penrose and Wallace had stated that they considered vinegar, applied to the inner surface of the uterus, the most powerful hæmostatic in use. They had never known it to fail either in their own hands or in those of their students.

Dr. L. E. Neale related a case from his own practice (hospital), of secondary post-partum uterine hemorrhage, occurring on the *ninth* puerperal day, and resulting fatally. The patient, an Irish woman, age 25 years, primipara, was delivered by low forceps operation, at the University Hospital, March, 1885. The cervix and perineum were uninjured, the placenta came away entire, the third stage being normal. A mild attack of puerperal fever readily yielded to appropriate treatment. She was considered out of all danger and in excellent condition, when on the *ninth* puerperal day, in the absence of all attendants, a violent uterine hemorrhage occurred and ceased spontaneously, leaving her moribund. She died on the following morning. Dr. N. considered the hemorrhage in this case too profuse and sudden to be explained otherwise than by some form of atony of the uterus. He had never attended a case of severe or dangerous post-partum hemorrhage (“*flooding*”) in his own private practice, but, from what he had been taught and had clinically observed, he thought the

immediate introduction of the hand in utero (the obstetrician's hand whilst attending a case of labor should always be aseptic), with or without ice, and squeezing the uterus between the hand without and the *fist* within, the quickest and surest means of relief. He would also use ergot hypodermically.

Dr. Williams remarked that some years ago he reported before the "Medical and Chirurgical Faculty" some cases in which he had used ergot hypodermically in post-partum hemorrhage. In one case he first passed ice within the uterine cavity, then his hand, and scratched the lining membrane, without producing any contractions. He then injected ergot into the thigh, and as soon as possible re-introduced his hand into the uterus, when, almost immediately, it contracted firmly. This was the case which suggested to him the hypodermic use of ergot. He considered the fluid extract of ergot a more reliable preparation than ergotine. He makes it a rule to instruct every woman, whom he is engaged to attend in labor, to have on hand chloroform and fluid extract of ergot, and always give ergot at the end of the labor.

Dr. H. P. C. Wilson said he always followed the rule laid down by Dr. Williams in requesting his patients to have chloroform and fluid extract of ergot on hand before labor begins; but he never gives ergot before the expulsion of the child, and only then when there is any indication of absence of prompt and firm contraction of the uterus. We have, in the hand introduced into the uterus, the means of promptly arresting post-partum hemorrhage, while other agents, to be used if necessary, have time to secure permanent contraction of the organ. He had confidence in the *hand* as a *curette*, in hot water and in ergot in the above cases, but he did not approve of giving ergot after every case of labor, as it insured to the large majority of women unnecessary suffering in excessive after-pains, and he only used it in cases where there were indications of the occurrence of excessive hemorrhage. He could recall one case where ergot by the mouth, rectum, and hypodermically, failed to control the hemorrhage, and when manipulation of the uterine cavity with the fingers was equally inefficient. The uterus would contract and expand again and again under these remedies, and the hemorrhage, with each expansion, was frightful. This woman was saved, when almost moribund, by passing the hand into the uterus, and with long finger nails raking the whole mucous surface thoroughly for several minutes. She lost no more blood after this manipulation.

In another case of post-partum hemorrhage, when ergot and the hand and ice in the uterine cavity failed, he had saved the woman, when cold and pulseless, by throwing very hot water into the uterus. In this case a pint or two of hot water would cause the uterus to contract and check the bleeding, but so soon as the irrigation was stopped the uterus would expand, and it was only after pulling the woman's hips over the edge of the bed, with a tub under her, and pumping in gallons of hot water, that he succeeded in producing permanent uterine contractions and arresting the hemorrhage. With the means now at our command, the doctor had come to the conclusion that very few, if any, women should die of post-partum hemorrhage.

Dr. W. E. Moseley had found intra-uterine injections of hot water a very safe and certain method of checking hemorrhage from the endometrium. So far it had never failed him. It must be used in large quantities and hot, not less than 115° or 120° F.

Dr. Taneyhill exhibited a five months' fœtus enveloped in its amniotic sac, with the placenta completely (in all its surface) attached to the sac, which was voided by Mrs. H. H. at 2 a. m., April 12, in consequence of having taken a long walk, and on returning slipping on an orange rind. She has bilateral laceration of cervix, has had three children, one miscarriage, and three premature births. No unusual symptoms supervened except profuse hemorrhage, which was checked by ice externally applied.

Dr. Neale said that Prof. I. E. Atkinson had recently presented him with a specimen, now in the University of Maryland, identical with the one exhibited, save that it was the result of a pregnancy probably a little further advanced. This was from a case of induced labor on account of advanced renal disease, and the method used by Dr. A. was Krause's, or the introduction of a bougie between the membranes and the uterine wall.

Dr. Ashley said the specimen presented by Dr. Taneyhill was an interesting one to him, from the fact that he had never seen a fœtus completely enclosed in the amnion, and expelled at so far advanced a period of pregnancy. He had often thought that this was the physiological method of delivery. He was led to this conclusion from an observation of parturition in the lower animals. He had frequently observed the act of parturition in the mare, in the cow, in the sow, and in the ewe, and he was struck with the fact that the young of these animals are delivered

into the external world, in the vast majority of cases, completely invested with the amnion. He witnessed some three or four years ago the parturition of some 30 or 40 ewes, and in very nearly every instance the young lamb was dropped with the amnion intact, and he also observed that where the amnion had been ruptured prior to delivery the act of parturition was more tedious. He did not know whether his observation was the correct one, but if such be the fact, and if this be the design of nature in the lower animals, is not the modern obstetrician at fault in rupturing the amnion? Should not nature be left undisturbed in all cases of parturition, unless there was some manifest purpose in an interference?

Dr. Miltenberger had had one case in which the fœtus, at full term, was born with the membranes entire. The child was born just before he entered the lying-in room, and on turning the bed clothes aside it was seen actively moving inside the unruptured membranes. The child did perfectly well.

Dr. Neale thought the practical gist of Dr. Ashley's and similar remarks was the question, is the practice, recently advocated by Dr. Byford, of maintaining the membranes intact after complete dilation of the os uteri correct or not? Dr. N. had brought this question before the Society at the last meeting, and all present who spoke upon the matter, including Dr. Mundé, had expressed opinions opposed to Dr. Byford's plan.

Dr. Miltenberger said that after reading Dr. Byford's paper he had carried out his theories thoroughly for two months, and was convinced that the membranes when left intact after full dilation of the os did no good, delayed the labor, and did not effect any dilation of the perineum, that part refusing to relax until after the head came down against it. The head, when well down in the pelvic canal, would fill it up so fully as to prevent any of the amniotic fluid from being forced down below it during the uterine contractions.

Dr. Williams thought leaving the membranes unruptured would only delay the labor, and that those cases in which the fœtus came away with the membranes entire were cases of unusually tough membranes. As an example of tough membranes he stated that in a case of shoulder presentation, in turning he was able to pass his hand up between the membranes and the uterine wall, and the membranes ruptured only when he grasped the foot.

Dr. Robt. T. Wilson exhibited forceps for the complete compression of the pedicle during removal of growths within the female urethra. The doctor said that the forceps were firm and secure in their grasp; and their weight being so very slight, that where hemorrhage was feared, they could be left attached, in the canal, and the patient not at all troubled by their presence. The patient could urinate and move about without difficulty. Where they were used, it was not necessary to apply a hæmostatic. The forceps could be taken apart and thoroughly cleansed. They had been tested in several cases, and had given every satisfaction. They had been left attached twenty-four hours and the patient did not object at all to their presence, they could also be used for the compression of the pedicle of growths about the vulva, vagina, and cervix.

Dr. Ashley remarked that Dr. Wilson's forceps were quite ingenious, and could no doubt be used to good purpose. He had once had an experience with a caruncular growth in the urethra which proved to him that the hemorrhage following the removal of these small growths could be very troublesome and alarming. The removal of a small growth scarcely larger than a grain of wheat, located about five-eighths of an inch within the female urethra, was followed by the most annoying flow of blood he had ever experienced. Almost every effort to control it was successful for only a few hours, after which time the flow would return. Finally, pressure with a large catheter accomplished the object desired, though this pressure had failed in the early treatment of the case. Dr. Ashley said he had recently removed three small polypi from the cervix uteri of three patients. In these cases hemorrhage was very profuse, but he had stopped it with Monsel's solution. In each of these cases the polypi were not larger than small filberts, yet they had occasioned profuse menorrhagia in each patient.

Dr. H. P. C. Wilson thought that the forceps of Dr. R. T. Wilson for arresting hemorrhage in the urethra after the removal of polypi or caruncles, would prove to be a very useful instrument. The bleeding after the removal of these little growths is sometimes very great and hard to arrest. With this instrument the hemorrhage is promptly and securely controlled and without much inconvenience to the patient. The use of Monsel's solution for arrest of hemorrhage in the urethra is to be avoided, because it frequently fails in its object, and then the canal is so contracted and blocked with clots of iron and blood that we are cut off from the use of other styptics.

CHICAGO MEDICAL SOCIETY.

OFFICIAL REPORT.

Stated meeting, April 19, 1886.

The President, E. J. Doering, M. D., in the chair.

Dr. G. C. Paoli read a paper entitled

The Reasons why Female Physicians are Desirable in Insane Asylums.

He demonstrated that the most eminent specialists in psychyatry in the United States are a unit in maintaining that female physicians are best qualified for treating the female insane. Many states have passed laws requiring one female physician to be allotted to each one hundred female insane in their asylums.

Dr. J. G. Kiernan said eminent authorities had already pointed the relation which exists between uterine disease and insanity. Popular opinion is growing in favor of the employment of female physicians in the treatment of the female insane.

Dr. Wm. T. Belfield reported nine cases of

Impermeable Stricture Treated by Electrolysis.

During the past two years he has treated thirty-seven cases of stricture by electrolysis; and except for strictures located within an inch of the meatus, and for strictures of large calibre elsewhere, considers it preferable to dilatation and urethrotomy for the following reasons:

1. It will pass through any stricture, however tight, rigid, long, or tortuous.
2. As a rule it causes no pain, bleeding, chill, nor urethral fever.
3. It is always devoid of danger.
4. Its effects are lasting.

In certain numerous cases electrolysis is not merely a preferable, but really the only practicable treatment. Such are, 1, old, rigid, cartilaginous strictures in men of middle or advanced age, where urethrotomy is dangerous and dilatation ineffectual; 2, impermeable strictures; 3, tight and rigid strictures with perineal or scrotal fistulæ.

Dr. Belfield then narrated the successful treatment by electrolysis of nine such cases. In three of these there was complete retention of urine, the bladder being distended above the umbilicus; these strictures were absolutely impermeable, to urine from within as well as to instruments from without. In each case a No. 10 electrode (French) was passed into the bladder in less than twenty minutes, permitting the immediate introduction of a catheter. In each of these cases perineal section would have been, without the battery, inevitable.

In the remaining six cases Dr. Belfield, as well as other surgeons, had failed in attempts to pass bougies into the bladder; yet as the patients were still enabled to force a feeble, dribbling stream outward, these strictures were theoretically permeable, though practically impermeable. In these also a small electrode readily entered the bladder in one or two sittings.

In one case, seen in consultation with Dr. Miller, the patient had a series of tight, rigid, impermeable strictures, and twenty-seven fistulous openings in the scrotum and perineum; he had submitted to both internal and external urethrotomy, and to numerous unsuccessful attempts at dilatation; was urinating every half hour, day and night. In fifteen minutes a No. 10 bulb entered the bladder; that night patient rose only once to urinate, and for the first time in several years the urine flowed entirely from the meatus and not from the fistulæ.

The unfavorable results obtained by various physicians in their attempts at electrolysis have been caused by the use of improper currents, whereby heat was generated and the urethra cauterized, causing violent inflammation and even extensive sloughing. When properly used, the heat produced is insignificant; with six to fifteen small cells and a weak fluid, the cicatricial tissue constituting the stricture is dissolved away but not cauterized. Since cicatricial tissue is but scantily supplied with blood, and is, therefore, poorly nourished, it yields to a dissolving current which is insufficient to disturb the healthy urethral tissues.

Dr. L. L. McArthur said he had treated with success by electrolysis one case in which numerous operations had already been performed. When patient came to him he could pass a No. 8 sound; used No. 9 electrode, and the patient can now pass No. 15 American sound. Never had any pain or difficulty in micturating since the operation.

Dr. M. B. Brown detailed two cases of impermeable and two of permeable stricture, in which he used electrolysis with good result.

Dr. C. Fenger said he must confess that he was somewhat surprised by seeing the announcement of Dr. Belfield's paper "nine impermeable strictures treated by electrolysis." He had tried electrolysis a few years ago, but never had any success from it. It surprised him that Dr. Belfield should meet with nine impermeable strictures in a very short period of time, while Sir Henry Thompson has only met with three impermeable strictures in his whole life. By hearing the

paper read, however, he understood that Dr. Belfield does not mean to say that the strictures were impermeable in the strict sense of the word—the only correct one—but only meant that it was difficult to pass any instrument through these strictures. Sir Henry Thompson, in his "Diseases of the Urinary Organs," of 1882, p. 28, says: "Impermeability can not be held to describe a character, a physical quality of the stricture itself, but rather indicates the quality of the surgeon who treated it." Impermeable stricture is a contradiction in terms; it is not heard of so much now as it was twenty years ago. Dittil, of Vienna, in speaking about relative and absolute impermeable strictures, says a stricture may be impermeable for one man, or at a certain time, and permeable for another man, or at another time. Other modern authors on surgery, as König and Albert, speak about the matter in a similar way.

The second surprise to him was the advocated treatment by electricity, or electrolysis. There has always been in his mind a suspicious halo of mysticism about the electrolysis, whether applied to the different forms of surgical tumors or to strictures of the urethra. He understands from the paper, that the electrolysis does not mean galvano-caustic treatment, although quite recently Jardin, of Paris, uses a small galvano-cautery knife for passing slowly through the stricture. Dr. Belfield warns very justly against cauterization. The non-caustic electrolysis is to me a very mystic process. Dr. Fenger remembers years ago of one of Billroth's clinics which he spoke about electrolystic treatment of venous angiomas of the face, that he expressed as the result of his experience the following: "The electrolytic needle has no more or other effect on the tumor in question, than the mere mechanical disturbance of the tissue elements, that is, than any other needle, not connected with a battery, would produce."

Frankly, Dr. Fenger said that the historical fate of electrolysis in strictures, as well as elsewhere, up to date, has invariably been the following: Ever since Tripier, in 1864, and Mallez, in 1872, applied the electrolysis in strictures of the urethra, this method of treatment has come to the surface once every two or three years, only to disappear again, and it has never been able to take any hold on the profession; not because it has not been tried, but rather because it has not been found superior, or even equal, to the other methods. Littel states that, on the rather promising representations of Tripier and Mallez, he tried electrolysis in three cases of very narrow stricture. It proved of no effect in any of the cases, and in one of them a local inflammation followed. Sir Henry Thompson does not even mention the electric treatment anywhere in his writings about strictures, but warns very emphatically against any method of cauterization. König says, in a very short appended notice, that only the short and soft strictures depending upon a polypus or warty growth of granulation-tissue are proper objects for cauterization, either chemical (Duchamp), or galvano-caustic (Middeldorf). Otis, our American authority in this line of surgery, does not mention electrolysis with a word.

Newman, of New York, (*Medical Record*, August 12–19, 1882), is not only the advocate of electrolysis in this country, but has written so assiduously and specified the method so minutely as to have it termed, in the foreign literature "Newman's method." In 1882, Newman's old and new cases numbered twenty-three only. In reporting Newman's articles for Virchow's *Jahresbericht*, Güterbock, of Berlin, says that "Newman's method has already, in 1872 and 1876, been criticised so thoroughly that not much more need be said about it." Dikmann, in New York *Medical Record*, January 5, 1884, reports twenty-eight cases. Gräf, in Norway, reports, in 1884, two cases treated by "Newman's method," and Verneuil, in 1884, recommends Jardin's "electrolyse lineavu"—that is, cauterization.

Thus the electrolytic treatment of stricture has been tried off and on for over twenty years, but has only taken hold here and there, sporadically, and for a short time. It has in the urethra, not any more than in the other fields of surgery, as yet to any extent replaced the more rational treatment by mechanical means.

The electrolysis may, however, have a further trial, and if the success in extensive resilient strictures, as in one of Dr. Belfield's cases, should prove to hold good for other cases of that kind, it is possible that this treatment will have a better fate in the future than it has had in the past.

(*To be continued.*)

A German doctor has been fined three hundred and seventy-five dollars for displaying in a public refreshment room a bill of fees to a certain gentleman, adding that the attendance was on his wife for a sexual complaint. Most continental laws recognize the obligation of doctors to keep the secrets of patients whom they attend.

EDITORIAL DEPARTMENT.

PERISCOPE.

Stone Sacculated in the Bladder of a Female.

Dr. Charles Williams thus writes in the *Lancet:*

Cases in which a vesical calculus is impacted in a cyst situated in the walls of the bladder are so extremely rare, that I consider it a duty to record this very interesting example:

A fine and healthy girl, aged three years, living in Norwich, came under the care of the late Mr. George Hutchison in the year 1873, having for several months previously suffered from very decided symptoms of stone in the bladder. It had been noticed by her mother that from the time of her birth she had experienced a difficulty, as well as occasionally severe pain in passing urine, and that sometimes she voided blood mixed with it, and was in the habit of straining so violently as to produce prolapsus of the rectum.

On sounding the bladder, which was an unusually capacious one, it was with some difficulty that a calculus could be detected. At the wish of the parents Mr. Hutchison resolved to remove the stone by dilatation. Mr. W. H. Day assisted at the operation, and I was requested to administer chloroform. The urethra was freely and quickly dilated with Weiss's trivalve dilator. There was considerable trouble to find the stone, and when found a still greater trouble to seize it with the forceps (and it was particularly noticed that, although the patient was thoroughly under the influence of the anæsthetic, the getting hold of the stone with the forceps occasioned severe straining); the blades could not be made to grip the calculus; they continually slipped off, bringing away pieces of the stone. At last it became absolutely necessary to ascertain what occasioned the difficulty. For this purpose the urethra was still further dilated, and the neck of the bladder was also divided with a probe-pointed bistoury. The stone could now be felt with the point of the finger, immovably fixed in the floor of the bladder on the patient's left. It appeared to be of the size of a pigeon's egg, and was enclosed in a sac, through the neck of which a small portion protruded into the vesical cavity, and it was off this nodule that the forceps so continuously slipped. Many efforts were made to dislodge it—first with a scoop, then with the finger, which could barely reach it, and next with the forceps; they all proved unsuccessful. Several portions were broken off the uncovered portion, but the main piece was left *in situ*, as it was considered undesirable to make any further attempt to remove it, the patient having been a long time under the influence of chloroform, and apparently in a very exhausted condition.

The next day the child had voided very little urine. A catheter was introduced, and a small quantity of sanguineous urine flowed out. She was very drowsy, and had been so since the operation. When roused she took milk and brandy very freely, but immediately afterwards became drowsy again; she did not appear to have recovered from the influence of the chloroform. The next day she died. No post-mortem examination was permitted.

I am induced to believe this child died of chronic chloroform-poisoning, and not from the effects of the operation, which was by no means roughly performed, and there was very little blood lost. She never thoroughly revived, but became comatose, and died in that condition. It is difficult to imagine what could have given rise to the formation of the sac; there never was an obstruction to the escape of the urine, such as stricture or prostatic enlargement might engender, for neither existed. We are taught that a cyst is usually formed by the straining necessary to expel the urine; the mucous membrane is forced between the bands of muscular fibres, hypertrophied in consequence of the strain to which they are subjected. Nothing of the sort can apply in this case, and it is not easy to believe that the stone was the cause of the cyst, which it might have been had it been situated close to the neck of the bladder. When impacted in this situation, the very pressure to which a stone is subjected by the constant and long-continued action of the bladder to expel it causes the mucous membrane to ulcerate through, and the stone is in due time forced into a cavity, which enlarges as the stone grows, and in this way it may form a tumor in the vagina, as was the case reported by me in the *Lancet* of November 7, 1885. An effort is then made by nature to contract the opening, which in this child was nearly accomplished; but the calculus was far from the neck of the bladder, and could barely be touched with the point of

the finger, so that a different explanation of the formation of the cyst is required; and as no examination was allowed to be made, it seems to me to be almost impossible to suggest in what way the sac was formed. Sabulous matter or a few urinary crystals may probably have been deposited originally in a mucous follicle, lacuna, or fossa, and gradually augmented in quantity, and in this way the sac enclosing the calculus may have been produced. The mother of the girl at four years of age suffered from stone, which was removed by the late Dr. Edward Lubbock; it was the size and shape of a walnut. She has suffered from incontinence since that time.

Enlarged Prostate and Retention of Urine; Relief from Injection of Cocaine.

Dr. James Rhodes thus writes in the *Brit. Med. Jour.*, May 1:

G. B., aged 60, tall and stout, had retention of urine, on December 20, 1885, from a greatly enlarged state of the prostate gland. I used catheter No. 8, and continued to do so for about fourteen days—twice, and sometimes thrice, daily. On one occasion, I was unable to attend myself; an assistant tried, but failed. After this attempt, the tenderness seemed to increase along the urethra, with constant acute pain in the prostate gland, although morphine was often given without relief. I decided to inject a grain of cocaine, dissolved in a drachm of water and rectified spirit, into the urethra, with a small syringe, forcing the solution down to the prostate by a little pressure. The relief was instantaneous. During that night, he had complete relief from pain, and the change, he said, "was heavenly." It was used on two successive nights with like results.

W. W., aged 65, of Glossop, had been troubled with stricture for twenty-five years. When passing urine one day, it stopped suddenly. Some one attempted to pass a catheter, but he was injured thereby half-way down the urethra. An abscess formed, and was opened in fourteen days. After this, micturition was difficult, and the stream until now had continued small. Four years ago, I passed a No. 4 catheter for him, with some difficulty; he had then a large prostate. At 6 p. m. on January 6, 1886, he sent for me to pass a catheter. I found a very bad state of things; not a drop of urine had passed for two days, and I could not use the catheter. There was extravasation of urine, which extended along Poupart's ligament and the upper part of the thigh, with great enlargement of the scrotum. I punctured the parts freely, and injected a grain of cocaine hydrochlorate in a drachm of water and rectified spirit, to relieve pain along the meatus, forcing this past the stricture down to the prostate gland. I then went home for a large curved trocar and cannula, to tap the bladder posteriorly, and took my son to assist. On returning, in less than an hour, I was surprised to find that the patient's pain was gone; and, in ten minutes after the injection was used, he passed over half a pint of urine. There now seemed no need to tap the bladder. On calling to see him in the morning, he had passed five pints of urine; and now continues to pass it in a free stream, better than before.

In both the above cases, as in others, I found good results from the use of the following medicine:

℞.	Quiniæ sulph.,	gr. viii.
	Tinct. ferri perchlor.,	℥iiss.
	Ammoniæ hydrochlor.,	ʒi.
	Aquæ menthæ,	℥ i.
	Aquam ad.,	℥ viii.

One ounce to be taken every four hours.

The man is now at work. There was sloughing of the scrotum and upper part of the thigh, but this has done remarkably well. If any medical men will try the cocaine, I am sure they will be delighted with the success.

Papain in Dyspepsia.

In the *Brit. Med. Jour.* Dr. George Herschell, in a note on this subject, says that he finds papaïn chiefly valuable in the following classes of cases:

1. *Chronic Stomach Catarrhs of Children.*—Every one of us is familiar with that state in which we find children at times, and which is very frequently called "biliousness." It is characterized by loss of appetite, languor, pasty complexion, loss of sleep at night, and irritability during the day. There is frequently frontal headache, and the urine is loaded with lithates. If this state continue for any length of time the child emaciates, the unhealthy mucus which sheathes the stomach and intestines preventing the due absorption of the food. Cod-liver oil and compound syrup of the phosphates, which are generally given for the complaint as soon as the child begins to lose flesh, are not assimilated. Sometimes a cough develops, and the child is supposed to have incipient phthisis. I have found these cases rapidly improve with the following prescription:

℞.	Papaïn (Finkler),	gr. ½–gr. j.
	Sach. lactis,	gr. j.
	Sodii bicarb.,	gr. v.

M. To be taken after every meal.

It is also advantageous to give a drop or two of tincture of nux vomica immediately after the meal in a little water. The papaïn probably acts by dissolving the mucus, and thus facilitating the absorption of the food.

2. *Acid Dyspepsia.*—This drug is extremely valuable in this form of indigestion. *a.* As it acts equally well in the presence of an alkali, a sufficient quantity of bicarbonate of soda may be given with it to neutralize the excess of acid in the stomach without impairing its peptonizing power. *b.* Its antiseptic action checks the abnormal fermentation to which much of the accompanying flatulence is due. *c.* An antiseptic can be given with it to increase this action. I usually order it in the following manner:

℞.	Papaïn (Finkler),	gr. ij.
	Sach. lactis,	gr. v.
M.	To be taken an hour after meals with the following draught:	
℞.	Sodii bicarb.,	gr. xv.
	Glycerin. acid carbolic,	♏viii.
	Spirit ammon. aromat.,	♏xx.
	Aq. ad.,	℥iss.
M.	Fiat haustus.	

It appears that, taken one hour after a meal, a smaller dose of papaïn is required to produce the same result than if taken with the food.

3. *Cases where Severe Gastric Pain Coming on Shortly after Eating is the Prominent Symptom.*—I have tried the drug upon twelve cases of this nature. Complete relief was given in ten, one case was partially relieved, and one completely failed to derive any benefit.

Apart from its internal use, papaïn will probably come into extensive use as a peptonizing agent, to prepare ready digested food and enemata, in the way in which pancreatin and pepsin are used at present.

Unconscious Impregnation.

The *Lancet*, February 20, says: "At the recent Manchester assizes a man named Jackson, a dentist, was sued for damages for the alleged seduction and consequent pregnancy of a young woman aged twenty-five. The facts, as stated in evidence, were so remarkable that it is not surprising the jury were discharged without giving a verdict. The case is interesting from a medico-legal point of view, and shows the danger of administering anæsthetics in the absence of a third person. It appears that the woman went to Jackson for the purpose of having a tooth extracted, and while under the influence of gas the defendant, according to the allegation set forth in the statement of claim, ravished her. The plaintiff at the time was engaged to be married, and it does not seem that she made a complaint to her intended husband of the supposed assault—in fact, she even allowed the banns of marriage to be published, though cognizant that she was *enceinte*. Two questions arise in connection with the case of the highest import. Is it possible for intercourse with a virgin to take place during the short period of insensibility and semi-consciousness following the administration of nitrous oxide gas? We take it that, although possible, it is in the highest degree improbable. But there can be no doubt that, granted the accomplishment of the act, the answer to the query, "Can unconscious impregnation happen under such conditions?" must be in the affirmative. Cases are on record in which women have conceived during sleep, and the state of anæsthesia induced by gas is only another form of sleep. If we are correctly informed of the facts, we cannot understand why the plaintiff proceeded against the defendant by civil process and not by criminal indictment; for if the story of the woman is true, surely the man was guilty of felony. Perhaps the fact that the plaintiff did not make immediate complaint of the alleged assault weighed heavily in the balance on the side of the accused. Such a charge as the one above referred to is difficult and may be impossible to refute, and consequently it is only just that the strongest corroborative evidence should be required to justify a conviction or a verdict for damages, or, failing that, there should be a complete investigation of all the collateral circumstances as regards the conduct of both parties *re* the charge, and also a searching inquiry into their general credit. From an impartial survey of the medico-legal and moral bearings of the case as reported in the *Manchester Guardian*, we cannot help expressing the opinion that upon the evidence before them the jury could scarcely have found for the plaintiff."

Eucalyptus as a Topical Agent.

Dr. P. T. Williams thus writes in the *Cincinnati Med. News:*

I have never seen, so far as my recollection serves me, eucalyptus recommended as a topical remedy in any of the medical journals, nor do I remember of ever having heard any of my professional brethren speak of having employed it in that capacity. I was led to use it over the inflamed surface in a case of erysipelas, by being told by an old sailor who, at an early period of his life, had

sailed through the southern seas of the eastern hemisphere, that he had been treated by a physician in some one of the East India islands for erysipelas by the external application of it.

I have, therefore, to report that in three cases of erysipelas, one affecting the face and right leg, another the face, and another the scrotum, the itching and burning sensation, and the exudation of the peculiar gummy discharge, were promptly arrested by the application of the fluid extract of eucalyptus.

In a case of caries of the tibia, with extensive inflammation of the skin, attended with the formation of numerous blebs and small ulcers, the happiest results followed upon the local use of the fluid extract of eucalyptus. In the cases of erysipelas it was applied, by means of a camel's hair brush, every four hours. In the case of disease of the tibia I employed it twice daily. In each of these cases appropriate internal treatment was made use of.

My experience with eucalyptus as a topical agent, of course, is too limited to base much of an estimate in regard to its value, but the seeming beneficial effects following in the few cases I have mentioned encourage me to believe that it can often be used with advantage locally—that there can be obtained from it all the benefits that are to be had by the employment of the tincture of iodine, solutions of nitrate of silver, salts of iron, etc., and that it can be made use of when these could not be, in consequence of some objectionable features attending their application. I purpose using it in other cases that may come under my care, and I hope others may try it, so that if it possesses any claims as a local remedy they may soon become established.

The Hair Roots as Indicators of Bodily or Mental Disease.

Dr. J. Pohl-Pincus, of Berlin, has recently, in a *brochure* entitled "Polarized Light as a Means of Recognizing Irritable Conditions of the Nerves of the Scalp," announced that by an examination of the hair roots by polarized light peculiar changes may be observed whenever the patient suffers from physical irritation or mental excitement. This statement is the result of investigations which have now been going on for twenty-five years, and the later observations in the course of the research have uniformly confirmed those made earlier. The hair bulbs are divided into three groups, as follows: Group A. If, in healthy conditions of the body and mind, the hairs that fall out daily are examined microscopically by polarized light, the enlarged bulbous end of the root will show a white contour, and a yellowish or brownish-red centre. Group B. In all irritable conditions of moderate grade, all painful conditions of any organ, also in emotional disturbances of moderate grade, without any apparent bodily disease, the bulbous end of the hair root increases in length and breadth (in proportion to the irritation), the central part appears under polarized light of a violet, blue, or bluish-green color, separated from the white contour by bands of yellow and red. Group C. In higher grades of bodily disease or mental disturbance, the bulb becomes still larger, and the bluish centre changes to green, yellow, or orange. A few hairs of the B and C. types are found in normal conditions, especially in those more advanced in life. Dr. Pincus gives thirty-one cases showing the effects of painful disease, but more especially of depressing emotions, upon the appearance of the hair root. The conclusion to be derived from these researches is that bodily disease or mental excitement causes circulatory disturbances, and in consequence a change in the normal nutrition and pigmentation of the hair. This is only in accordance with previous observation, and the chief merit of Dr. Pincus's plan lies in his obtaining a means by which very slight and temporary changes in tissue growth can be detected and approximately measured.

Urticaria Occurring in Infancy.

In a communication read before the Clinical Society of Paris (*La France Médicale*, August 25, 1885), Dr. J. Comby states that Prof. Bouchard, in his researches upon dilatation of the stomach, has observed that a certain number of these patients are subject to more or less annoying outbreaks of urticaria. It is not at all surprising that a disease which has for its principal and immediate consequence faulty elaboration of the ingesta should awaken cutaneous manifestations like urticaria, when we see temporary digestive disorder (*embarras gastrique* and indigestion) accompanied by the same eruptions. This urticaria, due to the lesions or functional disorders of the stomach (like those which supervene after tapping hydatid cysts) is very probably a toxic urticaria, due to the fact that the skin serves as a route of elimination to the poison elaborated in the digestive passages, and taken up into the circulation. This, at least, is the rational explanation which M. Bouchard gave to this phenom-

enon in a paper recently read before the Faculty of Medicine. Dr. Comby tried, in a certain measure, to apply to the infants coming under his observation the results which were obtained from adults by Prof. Bouchard. The dilatation of the stomach encountered so often among the latter, Dr. Comby had found with almost equal frequency among infants of the poorer classes, subjected from birth to defective alimentation. Among animals, also, he had found, as a consequence of dilatation of the stomach, multiple disorders in many of the organs and tissues. The diverse eruptions grouped by authors under the name of "*gourmes*" (prurigo, scald head, etc.) appear with extreme frequency in little patients with dilatation of the stomach; but, of all these eruptions, that which had struck him most by its objective and subjective characters is urticaria, of which he reports five cases.

Colles's Fracture.

Before the New York Surgical Society (April 12), Dr. L. A. Stimson presented a woman, twenty-three years old, who received a Colles's fracture of the right wrist four weeks before, for which she had been treated in the Presbyterian Hospital. The lower fragment was markedly displaced upward and backward in the usual manner. The displacement was reduced by traction on the hand and coaptative pressure, and the limb kept between anterior and posterior splints, of which the latter reached to the wrist and the former to the metacarpo-phalangeal line, and bore at its distal extremity a woolen bandage placed obliquely, over which the fingers were flexed, and by which the hand was kept in dorsal flexion. Since the last meeting of the Society, three weeks before, he had taken pains to have the fingers freely and frequently moved; this motion had at no time caused pain. The limb was taken from the splints that morning. The reduction was complete; even the styloid process of the radius was as low as on the other wrist—a result made possible, in his opinion, only by the absence of notable crushing of the spongy bone at the time the fracture was received. The fingers could be easily and freely flexed and extended; the range of voluntary motion of the thumb was less than normal; passive pronation and supination, through an arc of nearly 70°, were possible. The case, he thought, proved that voluntary and passive movements of the fingers during the treatment of Colles's fracture did not always cause rigidity of their joints.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. G. T. Maxwell forwards us a reprint of an article showing that the climate of Florida in summer is less heated than most of the northern cities, and is singularly exempt from cholera infantum. Hence he would recommend that state as particularly suitable as a summer resort for children.

——In a paper "On the Ethics of Female Sterility," Dr. A. Reeves Jackson, of Chicago, discusses a number of interesting questions in reference to barrenness, among others artificial impregnation, which latter procedure he very properly justifies.

——Dr. Frank H. Hamilton goes to some pains to prove that cremation is not at present a necessary sanitary measure. The argument seems superfluous, but is put with great fairness.

——In a reprint from the *Edinburgh Medical Journal*, Dr. J. L. Milton describes two cases of that malignant skin disease known as dermatitis ferox. In both the constitution was broken down.

——At the graduating exercises of the Jefferson Medical College, Dr. Theophilus Parvin delivered an eloquent address on "The Duties of the Doctor to Himself and His Patients," which has since been published in pamphlet form.

——Dr. C. F. MacDonald, in a reprint lately issued, describes a case of insanity following a gun-shot injury to the head.

——Dr. F. N. Otis, of New York, argues in an article before us that there is a positive limitation to the contagious stage of syphilis within three or at furthest four years, with or without treatment. This assertion cannot but excite considerable attention.

——Dr. E. P. Bernardy, of Philadelphia, in a late article brings forward a variety of evidence to prove the value of the biniodide of mercury as a disinfectant and antiseptic in obstetrical cases.

——Messrs. James W. Queen & Co., Philadelphia, send us their priced and illustrated catalogue of Ophthalmological Instruments, etc.; 66th edition.

——The Boylston prize essay for 1885 was written by Dr. Edward S. Stevens, of Lebanon, Ohio, and now appears as a neat

pamphlet. The subject is "The Best Preliminary Education for the Study of Medicine." The scheme is well worked out, and the suggestions are eminently practicable.

BOOK NOTICES.

Diseases of the Spinal Cord. By Byron Bramwell, M. D., F. R. C. P., etc.

Insanity and its Treatment. By G. Fielding Blandford, M. D., together with types of insanity; an illustrated guide in the practical diagnosis of mental disease. By Allan McLane Hamilton, M. D.

Hand-book of Practical Medicine. By Dr. Hermann Eichhorst. Vol. i. Diseases of the circulatory and respiratory apparatus.

The Genuine Works of Hippocrates. Translated from the Greek by Francis Adams, LL. D. Vol. i.

The four volumes whose titles are given above are the issues for the first four months of the present year of Wood's Library of Standard Medical Authors, published by William Wood & Co., New York city. It will be seen that they offer a wide diversity of contents. Dr. Eichhorst's hand-book is a very useful and tersely written synopsis of modern medicine. He is particularly full in giving clear directions as to treatment. The work of Blandford is classical, and the essay by Dr. Hamilton which is appended, is full of clear directions by means of which to establish a correct diagnosis in cases of mental alienation. The illustrations are in lithograph, and present in a striking manner the characteristic features of the faces of insane patients. Dr. Bramwell's monogram is especially noteworthy for the abundance and appositeness of its illustrations. It contains fifty-three colored plates and one hundred and two wood engravings, all well done. Considering the price of the volume, it is surprising to see such careful pictorial features. We need say nothing of the translation of the immortal Hippocrates, further than that any physician can still learn from it much that will instruct him in his daily life.

The Elements of Chemical Arithmetic, with a Short System of Elementary Qualitative Analysis. By J. Milnor Coit, Ph. D. Pp. 89. Price 50 cents. Boston: D. C. Heath & Co., 1886.

The difficulties of mastering the elements of chemical science are happily overcome in this volume by a perspicuous arrangement, and by the omission of all useless accessory details. It is divided into two parts, the first giving a series of problems in chemical arithmetic, together with the rules for their solution; the second setting forth the main and essential principles of qualitative analysis. The student can use the manual either for private study or for lessons in the classroom. It is exceedingly well prepared for either purpose.

The International Encyclopœdia of Surgery. A Systematic Treatise on the Theory and Practice of Surgery by Authors of Various Nations, edited by John Ashhurst, Jr., M. D., Professor of Clinical Surgery in the University of Pennsylvania. Illustrated with chromo-lithographs and wood-cuts. In six volumes. Vol. vi. New York, William Wood & Co., 1886.

The concluding volume of this extensive undertaking embraces a series of monographs on the injuries and diseases of the various surgical regions of the body, such as the œsophagus, rectum, bladder, urethra, ovaries, etc. There are also articles on osseous tumors, and other affections of the bones, on orthopedic surgery, on the construction and organization of hospitals, on military surgery, and on the history of surgery in general.

As heretofore, the authors of the monographs include eminent specialists, both American and foreign. In some cases they have been written in French or German, and translated for the American reader. The conscientious effort is always apparent to secure the opinions of one of the highest authorities in each branch which is brought up for discussion.

The manufacture of the work is in all respects satisfactory, a fine, slightly-toned paper being employed, and a sufficient number of chromo-lithographs and cuts being inserted to illustrate the text. A very elaborate general index of the whole work is appended, which will add greatly to its practical utility.

The Seat of Life.

A correspondent from Texas puts to us the question, "What is the Seat of Life in Man?" Probably if we answered, "Wherever function is in action, there is the seat of life," this would be most in accord with science. Life is not a *tertium quid;* it is not something apart and different from organic activity; it is simply the expression of this activity itself. When this activity begins, life begins; when it ceases, life ceases. This is all the physiologist knows.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

THE INTERNATIONAL CONGRESS.

At last the *Medical Record* has awakened to the truth about the International Medical Congress, and is willing to announce that the Congress will be held and will be worthy of attendance. We reproduce its editorial of May 15th:

"FOREIGN MEDICAL DELEGATES AND THE INTERNATIONAL MEDICAL CONGRESS.

"Many, indeed most of our foreign brethren, are in a state of mind as to what all the quarrel over the next International Congress means. And while in this condition of doubt and ignorance as to whether there is to be an International Medical Congress, or only a National Domestic Quarrel, they naturally do not care to plan for a trip here next year.

"To these gentlemen we would say: We have had in this country certain disputes, mainly over the question whether the Congress organization should be controlled by the American Medical Association, a society of about three thousand members, or by the medical profession of sixty thousand men. In this dispute the American Medical Association has conquered, but by methods which have caused the resignation and withdrawal of the great majority of the American physicians best known abroad and at home. There will be an International Medical Congress, but, according to the present outlook, a Congress in which many of America's best physicians will be absent.

"Still, we say to foreign delegates, you will meet a large number of able and hospitable gentlemen at the Congress, you will be made warmly welcome by all Americans, and you will hear no quarreling while you are in the States. *We know that many medical gentlemen in New York, Philadelphia, Boston, and other medical centres, debarred from receiving guests in an official capacity, will be glad to welcome all foreign visitors unofficially and pay them every hospitable attention.*"

We can only take exception to what the *Record* says about the control of the Congress. To our foreign brethren we would say that the fifty-five million people of the United States are controlled by a handful of men (Senators and Congressmen) who are the representatives of this vast aggregation of humanity. So the affairs of the International Congress are (and ought to be) controlled by the Association which is representative of the *sixty thousand* members of the profession of this country.

There is no reason why this sixty thousand

should not be members of the Association (provided they be *regular* and *respectable*); but as they are not, it seems eminently proper that the organized three thousand (as the *Record* computes it) should control the unorganized fifty-seven thousand. But the truth is that out of this sixty thousand a mere handful have had anything to do with the Congress.

In our profession, as in all others, there are comparatively few who have much interest in the profession outside of its bread-winning properties; the mass have taken no interest in the Congress controversy; while the *mass* of those who have, of those who believe in organized medicine, have conquered over the handful of malcontents. The closing paragraph in the *Record's* editorial (which we have italicised) we are glad to read, for it is additional evidence of what we have always believed, that the leading spirits in the revolt against the Association are *gentlemen*, who will do all consistent with the dignity of their position to welcome our foreign guests.

We congratulate the *Medical Record* that the dawn of truth and justness has at last broken in upon its *aristocratic* judgments, and only regret that it was not so favored before it labored so earnestly to make internal dissensions a matter of world-wide scandal. That they may know that many distinguished members of our profession will take an active part in the Congress, it is only necessary to refer our readers to the list of the organization as given on another page.

THE REPORT OF THE PHILADELPHIA DELEGATES.

We have received the "Report of the Delegates from the Philadelphia County Medical Society to the 37th Annual Convention of the American Medical Association," and have read it carefully. The more we reflect upon this unfortunate quarrel, the more reason we see to regret its occurrence. Upon each side are found most eminent men—men whose integrity, whose honesty of purpose, is beyond criticism, and who certainly thought and think that they were and are right in the diametrically opposed positions they have assumed.

That undue influence was brought to bear upon the judicial council of the American Medical Association (as intimated in the report) to help frame their rejection as the delegates of our County Society, we cannot believe for two reasons. First, we cannot believe the council willing to submit to such manipulation; and, Second, we cannot believe those who presented the protest willing to stoop to such methods.

To take the mildest view of the question, an unbiased mind must admit that there was, at least, a departure from custom and the law of precedence, in the manner in which this delegation was elected; and such being the case, a cloud hanging over their right to seats as delegates, we can but think that the judicial council acted wisely in denying representation to our County Society. It must be borne in mind that our Society refused to hear, *as a minority report*, the report which Dr. Knight desired to present, and we are therefore ignorant, comparatively, of the other side of the question. It is true that they granted Dr. Knight the right to present his report as a *communication*, but this he refused to do.

Let us have done with this unseemly bickering. The trouble in the County Society really arose from the Congress controversy; this controversy is now irrevocably disposed of, and should be no longer a live issue. Let us bury the hatchet, and when the Society reconvenes in the fall, let its gatherings be characterized by that good will hitherto so characteristic of the physicians of the "City of Brotherly Love."

THE YUCCA ANGUSTIFOLIA, OR SOAP-WEED.

The study of our native plants is as yet but at its beginning. The methods are costly and laborious, and to pursue them requires either the stimulus of large prospective commercial advantages, or a love of pure science which, alas! few manifest in this country. All the more heartily do we applaud such an example of the latter as is presented in a reprint of a paper from the *Transactions of the American Philosophical Society* before us. It is the report of an extended study of the chemistry of the *yucca angustifolia*, or soap-weed, by Miss Helen C. DeS. Abbott, whose previous researches in this direction are already well known to those familiar with this specialty.

The scheme adopted is that recommended by Professor Dragendorff in his treatise on "Plant Analysis." The parts subjected to examination were successively the bark of the root, the wood of the root, the green leaf, and the yellow base of the leaf. The extracts obtained by subjecting the various elements of the plant to the action of petroleum spirit are first defined and examined; the residual powders were tested by ether, alcohol, water, diluted soda, and acid solutions.

The product of these various processes, all of which are described with the most satisfactory completeness, was the discovery of two new resins, termed *yucca* and *pyrophœal*, a red crystalline coloring matter, four fixed oils, saponine, and other substances. A special quantitative examination for saponine of the wood of the root, specimens being selected from plants culled at different seasons, gave an average of about ten per cent. This derivative has many interesting relations, both to economic and abstract science, which we hope the competent author of this present paper will at some future day set forth with her accustomed accuracy and clearness.

SANITARY CONVENTIONS.

That the people of the nineteenth century are beginning to realize (practically) that "an ounce of prevention is worth a pound of cure," there is ample evidence. As Dr. Lindsley so well puts it, the duty, *that is to say, the chief duty, of State Boards of Health for some time to come*, will be to educate the masses in the science (for it is a *science*) of Hygiene, and to do so no better way can be devised than "Sanitary Conventions."

Following close upon the heels of our own State Sanitary Convention, comes the good news that a similar convention, equally successful, has been held in Kalamazoo, Michigan, and from the papers which we have received we learn that the *Press* of Michigan is not behind the *Press* of Pennsylvania in seconding the efforts of their respective State Boards of Health.

Michigan has an admirable Board, always doing good work, and we are quite sure that the time is close at hand when the "Science of Hygiene" will take its proper place as the most beneficent science known to man.

Notes and Comments.

Infantile Paralysis.

In the *N. Y. Medical Journal*, Dr. V. P. Gibney has an interesting article read before the Clinical Society on the subject of "Limitation of Therapeutics in Infantile Paralysis," from which we extract (*Peoria Med. Mo.*) the following paragraph or two:

What can be done to prevent the subluxations and deformities which arise from muscular and tendinous shortenings?

Without citing other cases, I may use the one already presented. We agreed upon keeping the limb and joints in normal position by means of light apparatus, and I am assured that there has been neither relaxation of ligament nor contraction of tendons.

For instance, it was directed that the hips should not be permitted to occupy long a position of flexion or adduction or abduction, and that at no time should super-extension be allowed. The child could sit in a wheel-chair, provided the feet were maintained at a right angle with the leg. It was understood that under no circumstances should super-extension of the knees be permitted. The feet were to be held at right angles with the leg when the child was out of the chair.

The case was kept under pretty close observation, in order that any tendency of the flexor muscles to contract should be promptly met by apparatus.

To summarize:

1. Avoid any undue stretching of the fibrous structures of the joint.

2. Do not permit long-maintained positions of the parts, by which muscles whose function has not been destroyed can become shortened.

3. Apply corrective apparatus when it is necessary to oppose contraction.

4. It is better not to leave these observations to the family.

Uncontrollable Vomiting During Pregnancy Cured by Feeding through an Œsophageal Tube.

The *Philadelphia Medical News* relates the following case of Dr. Bruenniche (*Centralb. f. Gynaek.*):

An unmarried woman with scanty, irregular menstruation, suffering severe gastric disturbance for two months, entered a hospital, and, under diagnosis of ulcer of the stomach, the possibility of pregnancy was denied. Soon after admission vomiting became so severe that all food was rejected and inanition was threatened. Alimentation by means of an œsophageal tube was now resorted to, and broth—followed by cold water, before withdrawal of the tube—was first fed to the patient without causing vomiting. Milk was then administered, and no vomiting being produced, it was followed by bouillon, etc., with like favorable results. After five days an attempt to swallow food caused reappearance of nausea and vomiting, and the use of the tube was again necessitated. Pregnancy was now readily diagnosticated. In three weeks the use of the tube was dispensed with, and the woman discharged cured.

A significant fact in connection with the

case is that it was only necessary to introduce the tube into the entrance of the œsophagus, showing that the location of the sensitive region, irritation of which occasioned the vomiting, was situated higher up in the digestive tract than the stomach.

A Radical Treatment for Masturbation.

Dr. J. C. Pennington, of Andover, Mass., writes as follows to the *Med. Record:* "I feel constrained to report a curious case of self-treatment which is worthy of the *Mikado.* The punishment was made to fit the crime in this wise: The patient, a boy of fifteen, being discouraged by his fruitless endeavors to free himself from the worst of all habits, deliberately selected the privy as the theatre of his operations, and, holding the offending organ by the prepuce with one hand, took aim with a small pistol, and shot it, with the other. The ball (22 calibre) entered on the dorsal surface; running beneath the skin, it entered the glans behind the corona, emerged on its dorsal surface, and again penetrated the prepuce before making its final exit. At the sight of blood the boy's heroism evaporated, and he screamed for help. As usual, the fair sex were most prompt in running to the rescue, and it was some time before a man arrived whom he could take into his confidence. Fortunately the urethra is not wounded, and a speedy recovery may be expected."

A Specific for the Treatment of Hernia.

Dr. Doroteo de Armas publishes an article in the *Union Médicale de Caraccas* (*Bulle Gén. de Thér.*, No. 28, 1885), in which he claims that the peasants of Venezuela produce a radical cure of hernia by means of a parasatic plant which grows on the *Bowdichia virgiloides.* The boughs of this parasitic plant are stripped of their leaves, and then scraped with a sharp instrument so as to remove all the inactive portions of the bark; the remainder is then chopped up and mixed with water to form a semi-solid paste. After the lapse of some time an extractive matter separates, which is at first greenish, but then becomes almost black. It is elastic, semi-solid, and capable of being drawn out in long filaments, which stick to the hands, and gradually harden when exposed to the air. The mode of employment is to spread a thick layer of this substance on a piece of linen, and, after having well shaved the skin, to apply it over the hernial tumor, where it is maintained from forty days to two months. Dr. Armas refers to two cases of cure with which he is himself personally acquainted. He believes that this mode of action is on the one side attributable to its contraction, and so renders it analogous in its application to a truss; and he believes, on the other hand, that it exerts special influence over the hernial rings.

Treatment of Acute Rheumatism.

The last number of the *Russkaya Meditsina* contains a communication from Dr. L. Drinevitski, of Rostoff-on-the-Don, who writes that for more than twenty years he has treated acute articular rheumatism with nitrate of potash, two drachms being given daily in raspberry syrup, and a dose administered every two hours. Together with this internal medication, he prescribes an ointment for use morning and evening of the following composition: Olei hyosc., 1 oz.; ung. hydrarg. cinerei, 2 dr.; ext. acon., 1 dr. He has tried all ordinary remedies, and finds that on the whole this plan of treatment is more satisfactory than any other, being especially valuable in those cases where salicylates fail to give relief. Generally the disease is brought to an end in from one to two weeks, according to its severity and the time the treatment was commenced. When commenced at the onset of the attack, and before more than one joint was affected, the others were usually spared altogether.

New Observations on Urethane.

The *N. Y. Med. Jour.* tells us that Coze, who has been conducting a series of experiments with a view to determining the precise physiological value of this new drug (*Bull. Gén. de Thérap.*, April 30, 1886), draws the following conclusions:

1. Urethane has a strong hypnotic action, causing complete muscular relaxation and, in full doses, anæsthesia.
2. It slows the pulse and the respiration, and lowers the temperature.
3. As it is only slightly irritating, it may be administered hypodermically.
4. It affects neither the secretions nor the general nutrition.
5. It is a physiological antagonist to strychnine.
6. It appears to be adapted to cases of convulsions, especially those of a tetanic character.

Subcutaneous Use of Morphine in Infantile Convulsions.

Dr. C. S. Scofield, of Boston, reports to the *Med. Record* the case of a child eighteen

months of age, previously healthy, whom he had been called to see on account of eclampsia. The child had been in convulsions for two hours, and had been given emetics, hot baths, and mustard to the feet, without any benefit. The writer at once administered one-eighth grain of sulphate of morphine, hypodermically, which was repeated at the end of twenty minutes—no effect having been produced by the first dose. This was also followed by no improvement, and a third injection was administered twenty minutes later. This was effectual in controlling the convulsions, and by the expiration of an hour from the time of administration of the first dose the child was sleeping quietly. When seen the following morning, the child had taken food as usual, and was apparently as well as ever.

The Injection of Oil of Turpentine into Old Sinuses.

From the *N. Y. Med. Jour.* we learn that Cecchini (*Annali Universali di Medicina*; *Abeille Méd.*) reports a number of cases in which he succeeded in causing the closure of old sinuous tracts by injecting into them a few drops of oil of turpentine with a common hypodermic syringe. The best results, he says, are obtained when the drug is used pure, but it may be mixed with some bland oil, or even with a solution of morphine, as the pain is sometimes considerable. By this simple treatment, the author has cured five anal fistulæ and six sinuses connected with carious bone. The turpentine is thought to exert a stimulating action on the walls of the sinus, whereby healthy granulation is promoted.

A New Case of Infection in Utero.

Dr. Zeissel reports in the *Wiener Med. Presse* a young married man who, in the commencement of the month of April, had connection with his wife the last time. The menses remained away, and the wife proved to be pregnant. On the 12th day of April he had connection with another woman, and contracted syphilis from her. The sore healed rapidly, but an induration developed which remained a considerable time. As he believed that without a sore he could not infect, he, on the 25th of May, recommenced intercourse with his wife. She contracted syphilis, and on the 31st of December, 1883, was delivered of a child, It showed evidence of hereditary syphilis, and died soon. Here we have a case demonstrating the possibility of a child begotten of a healthy father to become diseased through its mother, who contracts the poison during gestation.

Cure of Angiomata.

The *Weekly Med. Review* tells us that favorable results from the employment of Meckes' method for the cure of angiomata are reported by Negretto, in the *Gazette Méd. Ital. Lombard.* The method consists in painting the angiomata with a mixture of collodion and corrosive sublimate. The whole surface affected receives four coats of the solution. The application is renewed every fourth day until the angioma is cured. Negretto reports success in two cases of vast teleangiectasis of the face. A small portion of the tumor only was painted at a time. The application is not advisable where mucous surfaces are involved. Meckes' formula is four parts of corrosive sublimate to one of collodion. Negretto finds that two parts in thirty answer. A very good cicatrix results.

Puerperal Fever.

Dr. Hiram Corson thus writes of it in the *N. Y. Med. Jour.*, May 29: "Of this I can only say that if it is a disease different from peritonitis I know nothing of it. It is a disease exceedingly rare in the country. If it is caused by the germs which are so guarded against in cities and especially in hospitals, they are inactive if they exist at all in the country; and, therefore, the directions so urged by Dr. Elliott, Carl Braun, and others, are not needed with us."

Nitrous Oxide as an Anæsthetic.

M. Laffont, in a recent communication to the Paris Société de Biologie, stated that nitrous oxide is a most dangerous anæsthetic. He has since further prosecuted his experiments; and, at a subsequent meeting, confirmed his previous statements. He has found proof that nitrous oxide is not an anæsthetic, but an asphyxiating agent, as MM. Jolyet and Blanche have proved. When this agent is used by dentists to produce anæsthesia, hyperglycæmia, and glycosuria result. M. Laffont has verified these phenomena by personal experience. He has also ascertained that in animals these results take place before anæsthesia, during the period of deep breathing.

Diagnosis of Lead-poisoning.

As a proof of the assertion that lead is eliminated by the skin, Dr. Dumoulin, at the

Belgian Academy of Medicine, lately showed a patient suffering from chronic lead-poisoning, whose integument became blackened wherever it was moistened with a solution of either sulphite of sodium or sulpho-hydrate of ammonia. This seems a more certain means of diagnosis than the blue line on the gums.

Retraction of the Penis.

In *Vratch* is reported a case where a man's penis suddenly retracted until it disappeared under the pubic arch, leaving a depression something like the umbilicus. When seen by a physician the man had tied a string to the penis, fastening the other end around the thigh. After a few days the organ ceased retracting, the only treatment pursued being the administration of small doses of bromide of potash.

Treatment of Ivy Poisoning.

In the *Northwestern Lancet* Dr. Augustine Brown calls attention to a specific remedy for ivy poisoning which he described eight years ago in the *Medical Record.* This remedy is bromine, which Dr. Brown has employed with unvarying success in seventy-five cases, using the following formula:

℞. Brominii, gtt. x–xx.
Ol. olivæ, seu
Ol. amygdalæ dulc., f℥j.—M.

Sig.—Apply freely to affected surface four times daily. Wash with warm water and castile soap twice daily.

Valerian in Diabetes Insipidus.

Demange says in *L' Union Medicale* that diabetes insipidus is best treated by valerian in doses of two to four drachms of the powder per diem. This drug was highly praised by Trousseau, and has been revived since by Bouchard.

Correspondence.

Narrowing of the Colon.

Eds. Med. and Surg. Reporter:

In your journal of May 15th, I noticed an account of a case of narrowing of the small intestine, reported by Dr. Davidson. Having notes of a case somewhat analogous, which I determined to report at my leisure, is sufficient excuse—because of the apparent similarity—to warrant its appearance at this time. In July, 1883, I saw, in consultation, a young man, aged 20, who was taken sick in the county with what appeared to be a case of ordinary colic. He suffered greatly for about 48 hours with acute abdominal pain, which was accompanied by slight swelling of the abdomen, and vomiting of orange-colored matter. The bowels were open, though the evacuations were rather scanty and thin, and presented nothing unusual in character or appearance. This condition existed for several days, and on the fifth day I was called, there being no change except a partial subsidence of the pain. The countenance now wore an anxious expression, and the patient would retain nourishment and medicines for about two hours at a time, when the contents of the stomach would be voided with a gush (reminding one of a bucketful of water turned suddenly bottom up), of which the patient would have no previous warning, as nausea, etc. This state of affairs continued until death terminated the scene, on the seventh day, from exhaustion.

I will not occupy your space with an account of the treatment, but as the case proved so obstinate, and had the features of an obstructive disease of some character, permission was had to hold an autopsy, and accordingly, six hours after death, upon such examination the following facts were developed: The stomach was healthy, the walls thinner than usual from distention, and it contained about three pints of orange-colored fluid. The small intestine was distended by gas, and appeared *larger than normal,* but the colon, beginning about two inches from the ileo-cæcal valve, was narrowed its entire length to the region of the sigmoid flexure, at which point it became normal. There appeared to be a contraction of the circular coat of almost the entire colon, which reduced its calibre with very slight thickening of the bowel to an apparently uniform diameter of ¾ of an inch. The liver was normal; the gall-bladder contained about one ounce of dark-green bile. Otherwise nothing unusual was found. The difference in size of the large and small intestines was so striking as to impress one with the idea that they had changed places in this case.

The subject of this unique case usually enjoyed good health; was a machinist by occupation, and never before had any indications of abdominal disease of any kind. Here was a case difficult of diagnosis, and treatment of any kind would have been unavailing had the correct pathological condition been fully understood.

S. N. Myers, M. D.

Martinsburg, W. Va.

Labor Influenced by Mental Impressions.

EDS. MED. AND SURG. REPORTER:

On the afternoon of May 31, 1883, the writer was sent for to attend Mrs. S., æt. 39, in her twelfth confinement. She had had pains more or less severe for about thirty-six hours, and, although aggravating, they came on at long intervals, and did not at all act like those experienced during previous confinements. She was very despondent, and had a foreboding that she would not survive the ordeal before her. A digital examination showed a well-dilated os, and a somewhat large but not very tense bag of waters, which upon slight manipulation, broke; whereupon the liquor amnii escaped in tolerable quantity.

Being my first attendance upon the lady, I did not dwell upon the initial examination at length; but discovered in the presenting parts a softness and pliability to the touch, just the reverse of the "characteristic feel which the head supplies." A positive diagnosis being important as well as desirable, a second examination was soon proposed, when the nates, the ischio-rectal depression, and the anal orifice were distinctly recognizable, and a breech presentation was no longer a matter of doubt. The husband being told that the child's breech presented, imparted the information to the patient, upon whom the effect was highly unfavorable; for from that moment all labor pains ceased, and there was complete inertia of the uterus for four hours. No medicine of any kind was administered during that time, only moral means, alternate warm and cold applications to the abdomen, warm pediluvia, and change of position being resorted to for the purpose of overcoming the trouble, which, as will readily be understood, was purely of a mental nature.

At length, after some private conversation between the husband and wife, I was told that a consultation was desired, and that Dr. ——, a neighboring practitioner (with whom I could not conscientiously affiliate) had been selected by them for counsel.

I now informed them that, in view of their decision, I would remain till his arrival, and then leave the case to their choice. The husband started on horseback for the proposed counsel, and I made preparations for departure. As I carried my medicine and obstetric cases to the vehicle outside, the patient became impressed with the idea that I was going away, and she would be left without an attendant.

Immediately the servant-girl was sent to the door, with the request that I should come into the house quickly. I hurried to the bedside, and found my patient seized with a strong expulsive pain. After a moment's pause another followed, and then another, and in less than ten minutes' time there was born unto this mother a boy, alive and kicking, as the result of this decisive mental impulse, for such it certainly was on her part. It is needless to add that a messenger was sent to intercept the counsel.

D. B. HOLSBURG, M. D.

Granville, Ill., May, 1886.

NEWS AND MISCELLANY.

Pennsylvania State Medical Society.

The Pennsylvania State Medical Society was in session at Williamsport, Wednesday, Thursday, and Friday, June 2, 3, and 4. There were about 500 members present. The Society is growing in numbers and importance, and the members present were quite enthusiastic over its future. Soon after roll call on the first day, a protest was entered against the registering of the names of the Philadelphia delegates, as there were two sets of them present. The Philadelphia County Medical Society has two factions, and each faction sent delegates. The matter was referred to the Judicial Council for settlement, and Drs. Keene, Tyson, Parvin, Solis-Cohen, Jackson, and Parish were appointed to represent the Philadelphia delegates before the Judicial Council. Dr. Thomas H. Helsby, on behalf of the Lycoming County Society, delivered the address of welcome. He spoke of the growth of the society since the last meeting in this city, fifteen years ago, delivered some touching tributes to the members who had died during the past year, and reviewed the progress that has been made in enlarging the membership of the association.

The majority and minority reports of the delegates to the American Medical Society were read, and the reports of the delegates to the medical societies of Ohio, West Virginia, Maryland, Delaware, New Jersey, New York, and Massachusetts handed in. Reports were also read from the secretary, correspondents of library, treasurer, committee of publication, medical examiners of county societies, county medical societies, committee on collective investigation of disease, committee on medical education. A bill to be presented to the Legislature, relating to the requirements to be imposed upon physicians before they can practice in this State, was read. This provoked considerable discus-

sion, and at last it was agreed to postpone its consideration.

In the afternoon the convention was called to order at 2 o'clock, and Dr. J. M. Anders, of Philadelphia, delivered an address on "Hygiene and State Medicine." Addresses were also make by Dr. Charles E. Sajous, of Philadelphia, on "Laryngology;" Dr. C. W. Dulles, of Philadelphia, on "Pasteur and Hydrophobia;" Dr. Solomon Solis-Cohen, on "Inhalation of Compressed Air as an Aid to Nutrition in the Treatment of Pulmonary Consumption," and Dr. Edward Jackson, of Philadelphia, on the "Relation of Eye-strain to Headache."

After the addresses were made the question about the admittance of the Philadelphia delegates was brought up again. A hot discussion followed, and at last the following resolution was offered and passed: "That it is the sense of this society that when a protest is presented against the admittance of delegates from a county medical society this should not act as as a bar to their registration, but they should be registered upon presentation of such certificates as are provided for by Article III. of the Constitution, and not be deprived of the rights of delegates until the charges of the protest are established."

When this passed, the Philadelphia members registered, and the meeting adjourned. In the evening a reception and banquet were given at the Park Hotel.

The first business on the second day was the reading of the report of the Judicial Committee appointed to investigate the protest of Philadelphia members against the admission of delegates. The council had been in private session nearly all of the first day hearing both sides of the question. They reported that the protest was not sustained. This announcement was greeted with a round of applause.

Dr. John T. Carpenter, of Schuylkill, delivered an address on "Mental Disorders." He spoke of the causes of mental trouble and how insane patients should be treated. In his opinion only 20 per cent. of insane patients sent to asylums ever recovered. No doubt more could be saved if they had proper care. He spoke of the causes of insanity, and said that a great deal of it was due to our fast American life. He arraigned the newspapers for considerable of the crime that is committed. Boys too early become addicted to alcoholism and the use of tobacco, and this in time brings about softening of the brain. The strain of political excitement, speculation in stocks, loss of peace and means, all tend to break down the nervous system. Again, the doctor referred to the press, and exclaimed, "Who will reform the daily press? The person who brings about a reform and frees it from sensationalism, will be a benefactor of mankind."

When the speaker had finished, Dr. Lee, of Philadelphia, moved that county societies appoint committees on insanity, whose duties shall be to visit asylums, investigate the condition of insane persons, and see that proper treatment is given, and that proper sanitary arrangements exist in the building. The resolution was adopted unanimously.

Dr. Murdock, of Pittsburgh, read a paper on the "Relative Value of Manipulation and Reduction of Dislocation of the Hip." Dr. J. H. Packard, of Philadelphia, read a paper on the "Further Consideration of Tracheotomy." He illustrated his subject on a blackboard, and gave descriptions of the treatment of croup and diphtheria in children, and told how he removed the ulcerous mucus caused by those diseases. Dr. H. L. Orth, of Dauphin, addressed the Convention on "Surgery." "The Application of Moist Heat in the Treatment of Purulent Ophthalmia," was discussed by Dr. Albert G. Heyl, of Philadelphia. The paper was discussed by several gentlemen, who agreed with Dr. Heyl in the manner of treatment of the disease. The value of the application of heat, whether dry or moist, was advanced, instead of the use of mercurial solutions, where there is irritation to be removed from the eye.

Dr. A. Sydney Roberts, under the head of "Remarks on Flat-foot, with Description of a New Plant or Spring for its Relief," spoke of the frequency of spurious valgus or flat-foot, the pain and debility resulting from it, and the liability of the deformity to be mistaken for rheumatism, neuralgia, or even tarsal osteitis. He described the bony arches of the foot, and the part the second or supplementary one played in support of the superincumbent body weight, together with the changed relations of these parts in the acts of walking, running, dancing, etc. The relation of vessels, ligaments, and fasciæ as accessory supports were also described at some length; the weak point of the arch was located where the astragalus rested upon the os calcis, and that in occupations requiring continued standing and walking, the muscular and ligamentous supports of the arch became overtaxed and did not afford proper assistance to the bony arch, as a result of which permanent extension or flattening of the foot resulted.

In speaking of the morbid anatomy, the

author stated that in the congenital variety the flattening of the arch, which is incomplete at this period of life, is more apparent than real, owing to the associated valgus which is always present in these somewhat rare conditions. The causes of the acquired varieties were stated to be rachitis, infantile spinal paralysis, rheumatism, and tarsal or ankle-joint osteitis. Bow-legs and knock-knee produce flat-foot symptomatically. These cases generally occur, the speaker went on to say, in adolescence and in those whose occupation compels them to occupy the standing position for a long time. Their gait is characteristic, heavy and dragging; the knee is bent, while the feet are placed gingerly on the ground. In speaking of treatment, special attention was given to the so-called inflammatory form, the speaker stating that rest, which is essential, could be best attained by the use of tempered steel springs, so made that the convexity of the spring should be at that point where the arch of the foot is most flattened. A great improvement over the narrow spring which was let into the shank of the shoe had been suggested by Mr. Arthur Lea, in which the spring was much broader, longer, and in addition to supporting the arch of the foot, prevented internal rotation by the extension upwards of flanges from the main body of the spring. Dr. Roberts stated that he had made use of the tempered steel springs in upwards of forty cases, with the most gratifying results, in the relief of pain, disability, etc., finding them more convenient than the older forms of plantar support and ankle braces.

Before adjournment a motion was adopted that the treasurer urge upon county societies to aid the local committee in Washington in their arrangements to give the members of the Ninth Congress, to which delegates from all over the world will be present, proper entertainment. A preamble and resolution was read by Dr. Corson, relating to the management of the hospitals of Harrisburg, Danville, and Warren, and a resolution was offered for the appointment of a committee of twenty-one to memorialize the Legislature to change the laws so that the management of the hospitals will devolve on the directors instead of the superintendent.

Following are the officers appointed for the ensuing year: *President*—R. Davis, M. D., Luzerne county. *Vice-presidents*—Hobart Allport, M. D., Clearfield county; Isaac Kerlin, M. D., Delaware county; D. J. McKibbon, M. D., Schuylkill county; W. B. Lowman, M. D., Cambria county. *Permanent Secretary*—W. B. Atkinson, M. D., Philadelphia. *Recording Secretary*—H. Howard Hill, M. D., Bedford county. *Corresponding Secretary*—J. H. Musser, M. D., Philadelphia. *Treasurer*—Benjamin Lee, M. D., Philadelphia. *Committee of Publication*—W. B. Atkinson, M. D., Benjamin Lee, M. D., J. H. Musser, M. D., Edward Jackson, M. D., Philadelphia; T. H. Helsby, M. D., Williamsport; E. Enfield, M. D., Bedford; W. G. Weaver, M. D., Luzerne. *Judicial Council*—John H. Packard, M. D., Philadelphia; John Curwin, M. D., Warren; A. H. Shaffer, M. D., Mifflin.

The next place of meeting will be Bedford, Pa., on the last Wednesday in June, 1887. The Committee of Arrangements include A. Enfield, M. D., Bedford; W. P. S. Henry, M. D., W. T. Hughes, M. D., S. H. Gump, M. D., and J. A. Clark, M. D., Bedford.

Dr. John V. Shoemaker, of Philadelphia, read an address on "Medicine," followed by Drs. J. H. Musser and F. Woodbury, of Philadelphia, on "The Treatment of Summer Diseases in Children," and "Puerperal Hemorrhagica," respectively. Dr. W. F. Waugh, of Philadelphia, read an interesting paper on "Typhoid Fever." Dr. E. A. Wood, of Allegheny county, delivered the president's annual address in the evening.

The Society dined at the Williamsport Hospital, and in the evening they were the guests of Reno Post 64, Grand Army of the Republic.

The last session of the Society was held on Friday, June 4, at the Academy of Music. papers were read by Dr. R. Leonard, of Carbon county, on "Obstetrics;" by Dr. T. V. Crandall, of Philadelphia, on "Additional Causes of Subinvolution of Uterus;" by Dr. W. H. Parcels, of Mifflin, on "Puerperal Convulsions;" and by Dr. A. Enfield, of Bradford county, on "The Antagonistic Drugs to be Employed in Typhoid Fever." A motion was made to defer the reading of other papers, and that they be given to the Committee on Publication.

Dr. Green read a resolution extending thanks to the retiring officers for their efficient work, to the people of Williamsport for their entertainment of delegates, to the press for their elaborate reports of the transactions, and to the railroad companies for giving the delegates reduced rates. This was passed by a unanimous vote. A motion was made and passed for the appointment of a committee of five to confer with the members of the Legislature about a bill relating to vivisection for scientific purposes. Dr. Benja-

min Lee offered a resolution that the Convention views with deep concern the attempt made to overthrow the National Board of Health, and that the delegates present urge upon the members of Congress from their respective districts the importance of affording the Board proper support. The resolution passed.

The committee appointed on vivisection are Drs. Woodbury, Jackson, Wood, Pollock, and May. The Convention then adjourned. It is agreed that this year's session has been the most successful ever held. About 120 delegates after the adjournment marched to the Philadelphia and Erie depot, where they took the excursion train for Watkins Glen. The excursionists returned to the city in the evening at 9 o'clock.

Correct List of the Officers of the Preliminary Organization of the Ninth International Medical Congress.

For the reason given by the *Journal of the American Medical Association* for publishing it, we reproduce from that journal (issue May 29) the following:

As several of the leading medical journals have recently attempted to give their readers a list of the general officers of the Congress and the presidents of the sections without taking the trouble to secure correctness, we think it proper to reproduce the general officers of the Congress, the members of the Executive Committee, and of the Local Committee of Arrangements at Washington, and the Presidents of the Sections, as arranged by the Executive Committee at its meeting on the 3d and 4th inst. It will correct the errors published by others, and will be useful for reference by correspondents.

FOR GENERAL OFFICERS OF THE CONGRESS.

President—N. S. Davis, M. D., LL. D., Chicago, Ill.

Vice-Presidents—W. O. Baldwin, M. D., Montgomery, Ala.; Wm. Brodie, M. D., Detroit, Mich.; W. W. Dawson, M. D., Cincinnati. O.; J. A. Grant, M. D., Ottawa, Canada; E. M. Moore, M. D., Rochester, N. Y.; Tobias G. Richardson, M. D., New Orleans, La.; Lewis A. Sayre, M. D., New York, N. Y.; J. M. Toner, M. D., Washington, D. C.; the President of the American Medical Association; the Surgeon-General of the United States Army; the Surgeon-General of the United States Navy; the Supervising Surgeon-General of the United States Marine Hospital Service.

Secretary-General—John B. Hamilton, M. D., Washington, D. C.

Treasurer—E. S. F. Arnold, M. D., New York, N. Y.

Chairman of the Finance Committee—Richard J. Dunglison, M. D., Philadelphia, Pa.

Chairman of the Executive Committee—Henry H. Smith, M. D., Philadelphia, Pa.

Chairman of the Local Committee of Arrangements—A. Y. P. Garnett, M. D., Washington, D. C.

Executive Committee of the Congress—Henry H. Smith, M. D,, Chairman, Philadelphia, Pa.; N. S. Davis, M. D., LL. D., Chicago, Ill.; John B. Hamilton, M. D., Washington, D. C.; E. S. F. Arnold, M. D., New York, N. Y.; Richard J. Dunglison, M. D., Philadelphia, Pa.; A. Y. P. Garnett, M. D., Washington, D. C.; F. S. Dennis, M. D., New York, N. Y.; Abram B. Arnold, M. D., Baltimore, Md.; Wm. T. Briggs, M. D., Nashville, Tenn.; DeLaskie Miller, M. D., Chicago, Ill.; James F. Harrison, M. D., University Virginia, Va.; F. H. Terrill, M. D., San Francisco, Cal.; Wm. H. Pancoast, M. D., Philadelphia, Pa.; J. H. Callender, M. D., Nashville, Tenn.; A. B. Palmer, M. D., LL. D., Ann Arbor, Mich.; J. Lewis Smith, M. D., New York, N. Y.; E. Williams, M. D., Cincinnati, Ohio; S. J. Jones, M. D., LL. D., Chicago, Ill.; Wm. H. Daly, M. D., Pittsburgh, Pa.; A. R. Robinson, M. D., New York, N. Y.; Joseph Jones, M. D., New Orleans, La.; Albert L. Gihon, M. D., U. S. N., Washington, D. C.; Joseph P. Gray, M. D., LL. D., Utica, N. Y.; Jonathan Taft, M. D., Cincinnati, O.

Local Committee of Reception and Arrangement.—A. Y. P. Garnett, M. D., Washington, D. C., Chairman; the Surgeon-General of the U. S. Army; the Surgeon-General of the U. S. Navy; the Supervising Surgeon-General of the U. S. Marine Hospital Service; J. H. Baxter, M. D., U. S. Army; J. M. Toner, M. D., Washington, D. C.; N. S. Lincoln, M. D., Washington, D. C.; C. H. A. Kleinschmidt, M. D., Washington, D. C., and forty other members in the District of Columbia.

PRESIDENTS OF THE SECTIONS.

General Medicine.—Abram B. Arnold, M. D., Professor of Clinical Medicine, Baltimore, Md.

General Surgery—William T. Briggs, M. D., Professor of Surgery, Nashville, Tenn.

Military and Naval Medicine and Surgery—Henry H. Smith, M. D., formerly Professor of Surgery and Surgeon-General of Pennsylvania, Philadelphia, Pa.

Obstetrics—DeLaskie Miller, Ph. D., M. D., Professor of Obstetrics, Chicago, Ill.

Gynecology—James F. Harrison, M. D., Professor of Medicine, Obstetrics, and Medical Jurisprudence, University of Virginia.

Therapeutics and Materia Medica—F. H. Terrill, M. D., Professor of Therapeutics, San Francisco, Cal.

Anatomy—William H. Pancoast, M. D., Professor of General, Descriptive, and Surgical Anatomy, Philadelphia, Pa.

Physiology—J. H. Callender, M. D., Professor of Physiology, Nashville, Tenn.

Pathology—A. B. Palmer, M. D., LL. D., Professor of Pathology and Practice of Medicine, Ann Arbor, Michigan.

Diseases of Children—J. Lewis Smith, M. D.. Professor of Diseases of Children, New York, N. Y.

Ophthalmology—E. Williams, M. D., Professor of Ophthalmology and Otology, Cincinnati, Ohio.

Otology—S. J. Jones, M. D., LL. D., Professor of Ophthalmology and Otology, Chicago, Ill.

Laryngology—William H. Daly, M. D., Pittsburgh, Pa.

Dermatology and Syphilis—A. R. Robinson, M. D., Lecturer on Dermatology and Syphilis, New York, N. Y.

Public and International Hygiene—Joseph Jones, M. D., Professor of Chemistry and Clinical Medicine, New Orleans, La.

Collective Investigation, Vital Statistics, and Climatology—Albert L. Gihon, U. S. N., Washington, D. C.

Psychological Medicine and Nervous Diseases—John P. Gray, M. D., LL. D., Professor of Psychological Medicine and Medical Jurisprudence, Utica, N. Y.

Dental and Oral Surgery.—Jonathan Taft, M. D., Professor of Dental and Oral Surgery, Cincinnati, O.

New York Medical Association.

The Third District Branch of the New York State Medical Association will hold its second annual meeting, in the court house at Binghamton, N. Y., Thursday, June 17, 1886.

OFFICERS.

President—Frederick Hyde, M. D., Cortland.

Secretary—Chas. W. Brown, M. D., Elmira.

COMMITTEE OF ARRANGEMENTS.

Drs. J. G. Orton, Chairman, C. B. Richards, S. P. Allen, C. W. Greene, J. H. Chittenden, F. W. Putnam.

ORDER OF BUSINESS.

Morning Session, 10 *A. M.*

1. Report of the Committee of Arrangements. 2. Address by the President. 3. Report of Executive Committee. 4. Announcement of Nominating Committee.

The Committee of Registration will be at place of meeting at 9 a. m.

1. "Notes on some Forgotten, or Much-Neglected, Remedies and Therepeutic Measures," by Caleb Greene, M. D. 2. "Third Stage of Labor, with Special Reference to Retained Placenta," by H. C. Hendrick, M. D. 3. "The Ideal Physician," by Jennie Stevens Elder, M. D. 4. "Rectal Corrections," by Frank W. Ross, M. D. 5. Dinner at Hotel Bennett.

Afternoon Session.

6. "Aphasia," by S. M. Hand, M. D. 7. "Observations on Southern California as a Resort for Pulmonary Invalids," by Theron A. Wales, M. D. 8. "Two Cases of Trephining for Traumatic Epilepsy," by Carlos F. MacDonald, M. D. 9. "Fracture of the Base of the Cranium," by Frederick Hyde, M. D. 10. "Causes and Treatment of Pelvic Hæmatocele," by Ely Van De Warker, M. D. 11. "May Life be Shortened by the Medical Attendant in Incurable Patients to Abridge Intense Misery?" by Jonathan Kneeland, M. D. 12. "Splenic Leucocythæmia," by E. Lester, M. D. 13. "Uterine Hemorrhage during Labor," by B. T. Smelzer, M. D. 14. "Oxaluria," by A. R. Nicholson, M. D. 15. "Spinal Irritation as Observed in a Special Case," by Thurston G. Packer, M. D. 16. "Acute Peritonitis," by W. B. Marrow, M. D. 17. "Bright's Disease," by John H. Price, M. D. 18. "Eclampsia following Childbirth," by Jonathan Kneeland, M. D. 19. "The Shady Side and the Sunny Side of the Practice of Medicine," by J. M. Farrington, M. D.

Indiana State Medical Society.

Before the thirty-sixth annual session of the Indiana State Medical Society, which met in Indianapolis May 11, the following papers were read: "Diabetes Mellitus, with Cases," by Dr. Wilson Hobbs, of Knightstown. "Medical Properties of Fraxinus Americanus," by Dr. J. I. Rooker. "Etiology and Treatment of Acute Croupous or Lobar Pneumonia," by Dr. O. N. Huff. "Disinfectants," by Dr. Hibbard. "Laparotomy," by Dr. T. B. Harvey. "Emmenagogues," by Dr. E. Hadley. "Glimpses of a Few of the Ancient Beacon Lights of Medical History," by the President. "Urea," by Dr. C. S. Bond, of Richmond. "Heredity," by Dr. Rachel Bailey. "Why, as a Rule, Does One Attack of a Specific Disease Pro-

tect from another of the Same Kind?" by Dr. S. H. Collins, of Laurenceburg. "Some Remarks on the Relation and Duties of the Physician to the Public," by Dr. J. W. Milan. "Locomotor Ataxia," by Dr. J. S. Gregg. "Washing out the Stomach as a Relief in certain cases of Obstruction of the Bowels," by Dr. Guido Bell. "Stricture of the Urethra," by Dr. D. C. Bryan. "Foreign Bodies in the Bladder," by Dr. L. H. Dunning. "Cystic Disease of the Testicle," by Dr. A. A. Hamilton. "Etiology of Pneumonia," by Dr. E. S. Elder. "Tumors of the Brain," by Dr. A. Hensly.

OFFICERS FOR THE ENSUING YEAR:

President—G. W. H. Kemper, of Muncie.
Vice-President—W. V. Wiles.
Secretary—E. S. Elder.
Assistant Secretary—J. McLean Moulder.
Treasurer—C. B. Higgins.

Philadelphia County Medical Society.

FEMALE PHYSICIANS—ILLEGAL PRACTITIONERS.

The Philadelphia County Medical Society, at its regular monthly meeting June 2, balloted for twenty-five candidates for membership, and elected them all except Dr. Clara Marshall, a Professor in the Women's Medical College, and a well-known woman physician, who failed to secure the necessary two-thirds vote. Dr. Marshall's name had been proposed several times before, and the vote has always been against her. It was decided to push the prosecution of illegal practitioners, and money was contributed for that purpose. Three bogus doctors have already been sentenced to imprisonment and fourteen more are under indictment.

Lactated Food.

Among the analeptics this preparation holds a deservedly high rank. It has long been familiar to the British profession, and has received the approval of some of the most competent English physicians. It has lately been introduced into this country by Messrs. Wells, Richardson & Co., whose advertisement will be found in another column. From some observations on its use made at our wish by good observers, we are enabled to recommend it as one of the best artificial food preparations which have been submitted to us.

Pure Pepsin.

The doubt which many physicians harbor in reference to the effect of pepsin arises from their use of an article which is impure. We agree with several of our contemporaries in recommending to such the employment of the Crystal Pepsin, as prepared by Dr. Jensen, of Philadelphia. He has long and intelligently made a close study of the most scientific processes for obtaining this therapeutic substance in its greatest purity, and in a form least liable to undergo change. His success has been marked, and we can give personal testimony to the value of his product.

A Complimentary Dinner to Professor Pancoast.

A well-deserved honor will be the complimentary dinner tendered to the late Professor William H. Pancoast by the alumni of the Jefferson Medical College, The dinner will take place at the Hotel Bellevue on the 17th inst.

Items.

—Prof. Bartholow says that when the cause of jaundice has been removed, salicylic acid will remove the bile pigment from the blood more promptly than any other drug.

—Toothache, when caused by acidity of the saliva acting on the exposed nerves, is promptly relieved by a strong solution of bicarbonate of soda used as a mouth wash and dentrifice.

— An excellent local application for "swelled testicle" is a paste formed in equal parts of subnitrate of bismuth and water. It removes the pain at once, and gradually reduces the swelling.

—Dr. W. G. Watford (*Brit. Med. Jour.*) insists, after an extended trial of the drug, on the efficacy of arsenic as a prophylactic of scarlatina. The failure of belladonna in the same direction, will not prevent the putting of this new claim to the test.

—A report on the therapeutic value of pure terebene will be made to the Pharmacology and Therapeutics Section of the British Medical Association at its forthcoming meeting. This will probably determine the future of the remedy.

—In the past year the richest American merchant, H. B. Claflin; the richest American railroad man, W. H. Vanderbilt; and the richest American planter, Edmond Richardson, have died. It is notable that not one of the three died in his bed. One dropped dead at his desk, another in his hall, and the other in the street.

"Pallas Syringe." The most useful Instrument for Vaginal Medication and Irrigation.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

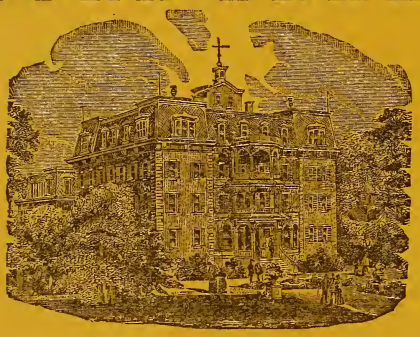
BURN-BRAE.



This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful Home.

NECROSIS OF THE HUMERUS—NECROSIS OF THE FIBULA—NECROSIS OF THE TIBIA—POTT'S DISEASE OF THE SPINE.*

BY H. R. WHARTON, M. D.,

Surgeon to the Children's Hospital, Instructor in Clinical Surgery in the University of Pennsylvania, Assistant Surgeon to the University Hospital.

John B., aged 10 years, whom I bring before you this morning, was admitted to the hospital during the latter part of the summer with cellulitis of the leg, which had gone on to suppuration. This was treated by incision to secure free drainage, and under this treatment he made a good recovery. About this time he complained of pain in the left shoulder, which he attributed to an injury of that part which he had received a short time before his admission to the hospital. The part became swollen and painful, his temperature rose rapidly, and for several days his condition seemed critical, My colleague, Prof. Ashhurst, saw the case with me, and we concluded that there was osteitis involving the upper epiphysis of the humerus; the whole arm became swollen and œdematous, and at several points abscesses seemed to be forming. Several incisions were made, which were followed by the discharge of pus and marked improvement in the local condition, and upon exploring the wounds thus made with a probe, rough or carious bone could be felt at the upper portion of the humerus. After the incisions were made, his general condition was much improved, but the swelling gradually extended down the arm, and although the disease originated at the upper epiphysis of the humerus, I now think that the whole shaft of the bone has become involved.

You will notice upon examining the arm several openings with pouting granulations at the upper portion, and also just above the elbow several other sinuses presenting a similar appearance. You notice also the induration of the soft parts, and upon careful palpation the whole humerus seems to be expanded or enlarged, and upon exploring their sinuses with a probe, I find that they lead down to roughened or carious bone. Such being the condition of the parts, I think the time has arrived when we should cut down upon the diseased bone, explore it, and remove whatever we find in a carious or necrosed condition. The patient being etherized, I first apply the Esmarch bandage and then the tube, and this you will find a most useful apparatus in operating upon cases of caries or necrosis of bone, as it renders the part bloodless and enables the operator to see the condition of the parts clearly. I next make an incision from just below the shoulder upon the outer side of the limb to the sinus just above the elbow, dividing the skin and superficial fascia. I now divide the deep fascia, and carry the incision down to the bone, being careful in the middle of the incision to leave a mass of tissue which I think contains the musculo-spinal nerve where it comes around the humerus, as I do not wish to divide this. I divide the periosteum and push it aside and expose the humerus, which I find much expanded, and cut some of it away with a curved gouge at the upper portion, and expose some small

*Delivered at the Children's Hospital, Philadelphia.

sequestra surrounded by gelatinous lymph, lying in the medullary canal. I now expose the whole canal by cutting away the outer wall of the bone, and thorougly clear it of these small sequestra and lymph which it contains.

The success of these operations depends largely upon the free removal of all diseased tissues, either hard or soft, and the removal of all overhanging edges of bone.

I now am able to pass a director from the upper part of the bone through a sinus which opens in the anterior portion of the axilla, As I do not wish to encroach upon the axilla, I will pass an oakum seton through this, and it will be kept in position for a few days.

Having washed out the cavity with carbolized water (1–40), I pack it with strips of antiseptic gauze, and apply over the whole limb a gauze dressing, and hold it in position by a bandage starting at the tips of the fingers and carried up to the shoulder. This bandage is applied quite firmly, so as to control any hemorrhage which might occur in the wound. The rubber tube is now removed, and you notice that the circulation is re-established in the arm. The case will be closely watched for a short time for hemorrhage, and should it occur, a compress of oakum and an additional firm bandage will be applied. But as no large vessel has been divided, this complication is not likely to take place.

NECROSIS OF THE FIBULA.

The next case I bring before you is this little girl, aged nine years, in whom you see a decided enlargement in the region of the right fibula, and in the line of this bone you see three or four small ulcers with pouting granulations.

Upon examining these with a probe, I find that it enters the cavity of the fibula and comes in contact with dead bone, and from the sensation imparted to my hand, I think there is here a loose sequestrum. The child being etherized, and the Esmarch apparatus having been applied, I will now make an incision over the fibula in the line of the sinuses. Displacing the tendons and muscles, I expose the thickened bone, in which I see several openings corresponding with the openings upon the skin. I now cut away the external aspect of the fibula, and expose a slender sequestrum extending from the external malleolus almost to the head of the bone. Having cut away a sufficient amount of the outer shell of the bone, I can now remove the sequestrum with bone forceps. The cavity I now clear of all debris, and the bony edges are now sloped off and the wound is thoroughly irrigated with a carbolized solution. The wound is now packed with carbolized lint and a gauze dressing is applied and held in position by a roller bandage. The rubber band is now removed, and you see the circulation is re-established in the limb.

The same precautions will be taken in this case as in the preceding one as regards hemorrhage. I here call your attention to the fact that this patient has also suffered from hip-joint disease of the left hip, and has had her joint excised on that side, and will notice what a fair range of motion she has in her new false-joint at the point of operation.

The necrosis of the fibula and the disease of the left hip-joint are here probably due to the same cause.

NECROSIS OF THE TIBIA.

The next case I show you is this boy, aged eleven years, in whom you notice an enlargement of the lower end of the left tibia, and a sinus which presents the very characteristic appearance which you see. He is suffering from a circumscribed necrosis of the left tibia, and I call your attention to the fact that he also is the subject of hip-joint disease of the right hip.

The case being etherized, and the means having been applied for the control of the hemorrhage, I now cut down upon the lower end of the tibia, and having divided and turned aside the soft parts, I expose the bone, which I find much expanded at this point, and can see an opening, into which I introduce a director and feel a loose sequestrum. I cut away the anterior surface of the tibia freely with a gouge, and you see I can now without difficulty remove this sequestrum, which is perfectly detached, with bone forceps. I cut away all edges of bone which overhang the cavity in which this sequestrum rested, and wash the wound out with a carbolized solution and apply the dressing in the same manner as you saw me do in the other cases.

The after-treatment of these cases of necrosis, or caries, consists in removing the packing on the second or third day; but really no definite time can be set for this, as the rule is to remove it as soon as it becomes loose; and the subsequent dressing consists in keeping the wound clean and lightly packed with lint, so that its surfaces may not come in contact and adhere, leaving a sinus.

These wounds of course heal by granulation, and if all the dead or carious bone be removed and care be taken to cut away a

sufficient amount of the overhanging edges of bone so as to permit of the soft parts being drawn in, in the contraction which follows, and if the simple details of after-treatment be observed which have been mentioned, these cases are very satisfactory in their termination, and when the parts are solidly healed we have resulting a depressed cicatrix.

Necrosis may result from osteitis or periostitis or osteo-myelitis, or it may result directly from an injury depriving the bone of its nutrition without the development of inflammatory symptoms. Necrosis resulting from the first-named cause is most frequently met with and runs a more chronic course.

As remote causes of necrosis, we have certain constitutional conditions such as scrofula and syphilis, and I called your attention to the fact that in two of the cases which you have just seen there was co-existing hip-joint disease. From traumatisms, as previously stated, necrosis may result directly, and I think they also frequently act as an exciting cause in the constitutional conditions just mentioned.

I would also call your attention to the history of the boy who had suffered from necrosis of the humerus, in whom the disease seemed to originate in an epiphysitis of the humerus following an injury of the shoulder. Under this name an English surgeon has described an inflammation occurring in children at the junction of the epiphysis and diaphysis of the long bones which may be followed by periostitis, osteitis, and osteo-myelitis, and is often confounded with arthritis.

POTT'S DISEASE OF THE SPINE.

This child, four years of age, is suffering with caries of the spine, and as you see the disease in this case is located in the lower dorsal vertebræ, in which region you can see a marked projection. This case has been treated by means of the plaster-of-Paris jacket, which I will renew before you to-day. The child is first supplied with a closely-fitting woven shirt, and a small abdominal pad is placed under it over the region of the umbilicus; the case is now suspended from a tripod by means of this transverse rod, which is furnished with arm-pieces and a halter, or hand support, the suspension is only carried to that point where the toes rest on the floor. The bandage, which is made of crinoline, into which plaster-of-Paris has been rubbed, is now soaked in warm water and applied around the body; it is started a little below the crest of the ilium and carried up to the axillæ. The most important point in the application of this dressing is to obtain a firm base for support upon the bony prominences of the pelvis.

Three or four rollers applied in this way will form a firm splint, and after it sets, we will remove the abdominal pad, and place the child in the recumbent posture until the dressing has become thoroughly dry.

At the present time much diversity of opinion exists among surgeons as to the value of this dressing, which was first brought before the profession by Prof. Sayre, of New York, by whose name it is generally known.

Although I do not think it has accomplished all that its introducer has promised for it, I certainly have seen it employed with the most satisfactory results; it produces fixation of the diseased bones and relieves them of the superimposed weight, thus preventing an increasing deformity, until nature brings about a cure by the deposit of bony callus around the diseased structures.

I do not mean to say that a properly constructed apparatus of steel and leather may not accomplish the same purpose, but on account of the expense of this dressing, it is impossible to use it in hospital practice. Jackets of leather and porous felt moulded from a cast taken from a plaster-of-Paris splint have also been used with good results, and have the advantage that they can be removed for purposes of cleanliness.

Where the disease involves the cervical or upper dorsal vertebræ, as is the case in this next case I show you, we use in addition a jury-mast fastened to the plaster splint from which is suspended a halter which supports the weight of the head.

In very young children suffering with caries of the spine, owing to the difficulty of getting any fixed points of support from the pelvis, which, in this class of cases, is poorly developed, we apply no apparatus, but depend for the treatment of the disease largely upon the recumbent posture.

COMMUNICATIONS.

HOME TREATMENT OF INEBRIATES.

BY T. D. CROTHERS, M. D.,
Superintendent Walnut Lodge, Hartford, Conn.

What to do when called to a case of acute intoxication where the patient is either in a state of stupor or delirium, is often perplexing. Many letters come to me in the course of the year from excellent physicians who

are not satisfied with their efforts, inquiring what can be done with these cases in their homes. The following is an outline answer to these questions, intended to be suggestive rather than otherwise.

The physician is only called in such cases where some acute condition appears or alarming symptoms that are new to the friends or the patient. He is called only as a last resort, and the facts of the case are always exaggerated or concealed. The statements of patient and friends are always misleading. This is the result of the theory of vice, wickedness, and weakness. If stupor is present, it should be remembered that fracture of the skull, concussion of the brain, cerebral hemorrhage, embolism, thrombosis, uræmia from Bright's disease, epilepsy, narcotic poisoning from other drugs than alcohol, head apoplexy, hysteria, may each one be mistaken for the stupor of drunkenness. The alcoholic exhalations should not be regarded as positive evidence of acute alcoholism or drunkenness. They may be present in any one of these conditions as accidents. If the patient is in a state of delirium, careful inquiry should determine the causes, and show that it was alone the effect of alcohol on the brain. Having ascertained these facts, the heart's action should next engage attention. If this is wavering and uncertain, all narcotics, and even stimutants, such as alcohol, ammonia, camphor, or the electric battery, are dangerous. If it is firm and steady, many and varied remedies can be used. In the former case, begin with a hot bath, either Turkish, vapor, or even a hot sponge-bath. Continue its use for some time with saline drinks as often as the patient will take them. It is a good plan to cover up the taste with tinct. of cinchona. The degree of the delirium and stupor must determine the active medical interference. If maniacal, always have a trusted attendant in the room, who will execute all orders and prevent any injury. Do not use chemical restraints in the form of chloral or other narcotics until the active stage of the delirium has subsided. Wait until the patient exhibits signs of exhaustion, then give freely lupulin or valerian, which as a rule are quite sufficient to bring on sleep and rest to the brain and nervous system. The physiological condition present is always one of depression, exhaustion, and derangement of the great nerve centres, associated with varied and complex states of congestion. Remedies which stimulate the secretions, including calomel and salines, are of the first importance. The only stimulants that can be given with success are hot milk, beef tea, or hot acid drinks. If the stomach is deranged, beef-tea or milk is often not tolerated; then acids or the salines with bismuth are valuable.

The hot bath and hot sponging give very marked relief in most cases. Free action of the bowels and kidneys and active perspiration also bring great relief to all the acute symptoms. The means used in each case must of course depend altogether on the conditions present. Opium in my experience has been both uncertain and dangerous. One-fourth of a grain of morphia has produced a very dangerous lowering of the heart's action, and in other conditions of the same case no effect was noticed. Opium in any form is also dangerous from the fact that it is quickly substituted for alcohol. In other cases, the effect of opium is more seductive than alcohol, and the relief more positive, hence it is used ever after. Chloral is also dangerous, because of its uncertain action on the heart. The bromides are cumulative and depressing, and the various other narcotics are uncertain and irregular in their action. When the acute symptoms of intoxication subside, craving for spirits and various morbid impulses and delusions appear. Various remedies have been found of value to allay this craving. The greatest skill and tact, as well as therapeutic resource, will be requisite. I find that small doses of a combination of chloral, bromide, hyoscyamus, cannabis indica, with a solution of bark, very valuable given at night. Lupulin, cinchona, nux vomica, and caffeine are very useful, and can be given in many ways and forms. The mental treatment of the case grows in importance as the symptoms decline. The case is more than alcoholic poisoning, it is an insanity of the most dangerous insidious character. An insanity that is largely unknown, and must be determined by the physician from the facts and circumstances of each case. The emergency of acute intoxication is only a small part in the history of the case; this should be the starting-point for the treatment. The patient and friends should be made to understand that the drink craving and impulse is a physical disease, and curable by the use of means long continued; that the causes and progress of this malady are not matters of chance and controllable by the will and disposition of the person; that they depend on states and conditions that can be known and remedied: physical and psychical states, which the patient cannot understand, but are clear to the physician.

When the friends and patient realize this

fact, and the physician makes a careful study of the case, using means and remedies to meet all its conditions, then acute intoxication will not occur, and the progress toward recovery will be positive and distinct. The home treatment of inebriety is as practical as typhoid fever or rheumatism. The results will be far more satisfactory, and the restorations as numerous. The great obstacle is sentiment and the moral theories of the origin and cause of inebriety.

This is the future field for medical triumphs and discoveries. The empirical efforts of reformers and moralists must give way to the exact studies of medical men and scientists. What is needed to-day are facts; and physicians who make all these cases of inebriety a careful study, will find most positive indications for successful treatment in a vast variety of means and therapeutical measures that are now unknown. My experience of over ten years, exclusively devoted to this study, and based on the study of a very large number of cases from all parts of the country, fully sustains the following conclusions:

1. The home treatment of inebriety is at present confined to measures for relief of the acute symptoms of intoxication. These means are often empirical, and should not include narcotics, except in special conditions and cases.

2. Home treatment of inebriety, where the family physician can become acquainted with all the facts of the history, and know the influence of the surroundings and apply the means of prevention, gives the greatest promise of cure.

3. Inebriety must be fully recognized as a disease requiring exact means and remedies for its removal. Then the physician can bring to his work an intelligent congregation of the friends and the patient himself, and the cure will be a matter of certainty.

4. Inebriety, as a disease, is curable to a large extent, but with the means used by the moralists and reformers it is practically an incurable malady. Inebriety, scientifically studied and treated at home, can not only be prevented, but cured, in a large proportion of cases.

—Dr. A. Walker says, in the *British Medical Journal:* "In a number of cases, strychnine administered along with iron for a month before labor, has exerted a remarkable influence in preventing post-partum hemorrhage, where severe flooding has occurred in previous labor."

CHRONIC CYSTITIS.*

BY P. S. CONNOR, M. D., LL. D.,

Professor of Surgical Anatomy, Medical College of Ohio, Surgeon to the Cincinnati and Good Samaritan Hospitals.

In a state of health, the bladder admirably performs its functions, holding the urine till such a time as micturition may be convenient or proper; but let there be a tumor of the bladder wall, a retained foreign body in the cavity, or an obstacle to the ready outflow of urine, and sooner or later there will be developed a state of chronic inflammation, with associated changes in the chemical constituents of the fluid. He recommended the finding of the cause and its removal at the earliest possible moment. If the kidney, therapeutic or operative measures must be adopted accordingly. If a foreign body in the bladder, it must be extracted. If a urethral stricture, dilate, divulse, or divide it.

Because of the ready removal of the cause in cystitis produced by stone or stricture, these cases, if not so long in duration as to have involved the kidneys, can be cured with comparative ease.

If the irritation is excited, maintained, or aggravated by the condition of the urine, in proportion as it is lessened is the morbid state diminished. This can be effected by increasing the amount of urine, which flushes out the cavity and distributes and carries off the pus. Some infusions owe their good effects to the cleansing of the bladder by the increased amount of urine passing through. For like reasons, washing out the bladder by injections acts very well, provided it is properly done and with a suitable fluid. The instrument must be clean in the fullest surgical sense of the word; the fluid warm, and such as to arrest and prevent decomposition. Theoretically the weak sublimate solution is the best that can be employed, but it is found not infrequently to be badly borne. Care must always be taken not to throw in the fluid too rapidly or too strongly, and if a single-current catheter is used, not to over-distend the bladder.

Cystitis in elderly men, arising from enlargement of the prostate, acts as does a stricture. The indications for treatment are the complete emptying of the bladder at regular intervals and with the least possible effort to the patient. Catheterization should take the place of natural evacuation. The patient may be able later to lay aside the instrument, but as a general rule, he will em-

* Abstract of paper read before the Cincinnati Academy of Medicine.

ploy it his lifetime; preferably the soft instrument, and always properly disinfected. In very many cases the chemical changes in the urine are due to bacteria which are carried in on the catheter, and it is because of the germs thus introduced that the frequent use of the instrument has long been recognized as likely if not certain to be followed by putrefactive changes in the urine, and an aggravation of the symptoms. In the older and severer cases, when the general hypertrophy of the prostate is great, and the basfond of the bladder consequently deep, and the residual urine in decided amount, catheterization and antiseptic irrigation are the essentials of treatment. Sometimes the muscular coat becomes so enfeebled as to permit of over-distension, at other times it becomes excessively intolerant of fluid, which excites a spasmodic, painful, imperious desire to urinate. This condition may be associated with and dependent upon prostatic hypertrophy, very apt to be of the ball-valve variety, or complicated with urethral stricture. It may depend upon the bladder tumor, or upon tubercular disease of the prostate, or the seminal vesicles. The habits and mental state of the individual sometimes markedly affect the intensity of the irritability. Permanent retention of the catheter where there is difficulty in introducing the instrument from the size or direction of the canal, or over-sensitiveness of its membrane, is, in the essayist's opinion, improper. Any catheter will soon become encrusted, cannot be kept antiseptic, and will almost certainly increase the irritation. In severe cases operative interference is often strongly called for, and is capable of accomplishing much. The most important element in the treatment of cystic affections is rest. Open the contracted urethra by sound or knife, and the pre-existing inflammation will generally rapidly diminish or altogether disappear. Extended experience has demonstrated that parenchymatous injections of the enlarged prostate are of no value to produce shrinkage. I am becoming more and more convinced that in all severe forms of chronic cystitis in the male, either perineal section or supra-pubic cystotomy should be made. By draining off the urine as fast as it comes into the bladder that rest is secured, which above all else is the essential element in treatment. If the cystitis depends upon a vesical tumor, the perineal operation permits of the determination of the location, size, and nature of the neoplasm, of its removal if practicable, and under all circumstances of the cleaning and draining of the cavity. In young subjects with cystitis dependent upon local tuberculous deposits, dilatation of the prostatic urethra, or division of the gland, affords more relief, and that more speedily, than anything else. Many, especially of the French school, urge that the opening into the bladder should be supra-pubic, and there are unquestionably advantages in this operation over the perineal one, with, however, associated disadvantages.

In any and all forms of chronic cystitis, the prime indications of treatment are to remove the cause and give the organ rest. Just in proportion as these indications can be fulfilled will relief be afforded and a cure effected.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Special meeting, April 15, 1886. The president, B. F. Baer, M. D., in the chair.

Dr. M. Price reported two cases of

Emmett's Button-hole Operation.

I desire to call the attention of the Society to a novel operation for the diagnosis and treatment of urethral and vesical diseases and accidents incident to parturition, devised and practiced by Dr. Emmett, of New York, for the past six years. In the last edition of his gynecology he treats the subject elaborately, and gives it, as in his judgment the most rational treatment for prolapsus of the mucous and submucous tissues, urethrocele, lacerations of the urethra from dilatation or injuries in labor, gonorrhœal inflammation, and abscess in the urethral wall.

I desire to report two cases of this operation, where no other treatment, in my judgment, would have been of the slightest benefit to the patients. The operation recommended by Dr. Emmett is what he designates as his "button-hole operation of the urethra," and may be performed either in the Sims's position or in the lithotomy position. The operation consists in opening the urethra from three-fourths to one inch, midway between the urethral orifice and the neck of the bladder, thus giving ample room for inspection of the canal for any growth or condition requiring drainage or operative procedure. In those cases where the opening is made for diagnostic purposes simply, the opening may be closed with sutures, or be allowed to close in its own way. Many cases of urethral irritation are wonderfully bene-

fited, and most of them entirely cured, simply by the free drainage it allows. The mucous membranes of the urethra and vagina are tacked together in these cases to prevent retraction. In the operation for urethrocele, the urethral opening is made through the pouch or dilated portion of the urethra, while a block-tin bougie is held in the bladder. The opening is continued down into the mucous membrane covering the sound, and a sufficiently large piece of the mucous membrane of the vagina removed to insure the removal of the pouch. The mucous membrane is then taken under the sound and drawn through the button-hole opening, so as to obliterate the redundancy of mucous membrane; sutures are then passed from the vaginal surface to the block-tin sound and back on the opposite side in the same position—all the sutures being thus introduced before cutting away the redundant mucous membrane held by a tenaculum in the hands of an assistant. This is to prevent the possibility of failing to incorporate the mucous membrane of the urethra in the sutures, and so failing to secure a perfect result, inasmuch as it is the mucous membrane which, on account of its diseased condition, is giving the most trouble. This is also the operation performed for prolapse of the mucous membrane; its redundancy being pulled through the button-hole opening, back from the meatus and there fastened. The redundancy is then cut away, instead of cauterizing it as in the past.

The first case is that of a lady 32 years of age, the mother of four children. The last labor was very brief, as the woman was delivered with forceps in the hands of a medical man who had another engagement, and could not be delayed. This was four years ago. The woman, when she came into my hands, was suffering from a double laceration of the cervix, which was torn back to the vaginal vault; with laceration of the perineum back to the sphincter; and with a urethrocele that would have held two drachms of urine. There was also quite a protrusion of the mucous membrane of the uterus: what Emmet calls "hemorrhoids of the urethra," from constant straining to pass urine. This woman had suffered constant tenesmus or bearing-down pains ever since her confinement, with inability at times to go more than half an hour without passing urine; at other times she was compelled to micturate every few moments; the urine passing with the greatest difficulty.

This was making great inroads upon her health. She had consulted quite a number of physicians, and was treated, from what I understand, for "cystitis" and "ulceration of the womb." This, I believe, was the diagnosis of her trouble by the gentleman who had rendered her such efficient service at her delivery. The patient was operated on after the method of Dr. Emmet. An opening one and one-fourth inches in length on the vaginal surface and three-fourths of an inch in the urethral wall was made, and the superfluous mucous membrane both from the urethrocele and from the mouth of the urethra drawn through the vaginal aperture and the sutures put in before cutting away the redundancy of tissue. Seven sutures were applied, and a perfect result was obtained in oneweek. When the sutures were removed, they were all found in a space not larger than the end of my thumb in consequence of the contraction of the tissues. The woman passed her water ten hours after the operation, and continued to do so afterward without pain or discomfort. At the present time, three months after the operation, she says she is better than she has been at any other time since her last labor. I would also state that the perineum and cervix were also repaired at the same time. Silk-worm-gut sutures were used in this case.

The second case is one of great interest from a medico-legal point of view, as the cavity of the urethrocele was lined with a pus-secreting membrane. The patient, although under my care, was not examined until after the urethrocele became very troublesome. I then learned that difficulty from this source, gradually growing worse, had been experienced for four years. These facts were not ascertained until the husband had repeatedly presented himself for treatment of a mild urethritis which always developed after sexual intercourse. His condition had been attributed to other than legitimate causes. After a considerable number of attacks, he began to inquire the cause of his affliction. Having been asked the question as to "foreign relations," he stoutly denied any such cause, though he admitted that he had suffered from gonorrhœa early in life, but had been completely cured long before the time of his marriage, some fifteen years ago. He was then asked to have his wife present herself for examination at my office. I found her suffering from laceration of the cervix and a urethrocele. The urethrocele was exceedingly tender to pressure and had the feel of a fibrous growth; no fluctuation could be detected upon light handling in examination. A pus cavity was suspected from the painful character of the tumor and the husband's condition. Re-

peated attacks of urethritis following sexual intercourse indicated an unusually irritating discharge from some source, and as the mucous surface of the vagina and cervix was in a healthy condition, and the discharges mild and unirritating, there could be but one rational explanation of the husband's condition, viz., a suppurating sacculated condition of the urethrocele, with periodical discharges of pus. Examination under ether fully confirmed the suspected pathological condition. The urethrocele was thickened, corrugated, and filled with purulent ammoniacal urine. The patient was placed in Sims's position, and the operation was performed as detailed in the other case, except that the pus-secreting membrane was carefully removed with the scissors, and the edges of the healthy mucous membrane were picked up with a tenaculum and the sutures of silk-worm-gut introduced as in the case before cited. A perfect result was obtained, removing all irritation of body and mind.

Dr. Joseph Price reported for Dr. Barton Hirst a cure of

Vulvo-Rectal Fistula from Violence During First Coition.

The patient, a young woman of twenty-two, presented herself at the gynecological clinic of the Philadelphia Dispensary, with the following history: Previous to her marriage, which took place eighteen months ago, she had been a perfectly healthy woman. From the first attempt at sexual intercourse with her husband, which caused her to suffer such acute pain that she almost fainted, she dates all her trouble. The sexual act was also followed by severe hemorrhage, which persisted for a month; the passage of feces and flatus per vulvam was at once noticed. Every repetition of the sexual act for the next two or three weeks was followed by renewed bleeding, and even at the present time she suffers severely during intercourse. The passage of the fecal matter through the vulva gradually increased in degree, until the rectum was evacuated entirely through the vulva. There has been entire inability to retain flatus and feces.

Examination.—The finger, on entering the vulva, passes at once into the rectum through a patulous opening of sufficient size to admit two fingers. Inspection shows a perfectly intact crescentic hymen of moderate thickness and rigidity, having a small anterior opening. Immediately in front of its posterior attachment is an irregular, transverse tear, an inch and a half in its longest diameter, with thickened and everted edges, extending backwards and upwards for about one and a half inches, exposing to view the mucous membrane of the bowel. The vagina is small and has evidently never been entered. The operation proposed by Dr. Joseph Price, and done by him March 16, 1886, consisted in freshening the edges of the tear, partially loosening the hymen from its attachment and using it as a flap to supply the deficiency of tissue. Spotted silk-worm gut sutures were used, and the closure after the operation was complete and resulted in perfect union. This form of injury to the vulva is very rare, for although sixteen cases* of rupture of the vagina have been reported during late years as occurring during coition, only one of them, recorded by Blumenthal and operated on by Sir Spencer Wells at the Samaritan Hospital in 1860, bears any resemblance to the present case, which from the careful analysis given it by Dr. Harris is without doubt one of vulvo-rectal fistula. This form of fistula is much less common than the recto-vaginal. The case here reported is of especial interest, from the fact that the traumatism undoubtedly occurred during first coition; from the virginal condition of the hymen, and from the long time during which sexual relations were maintained under circumstances which must have been disagreeable to both husband and wife. There was no sign or suspicion of specific taint in either man or wife.

Dr. Harris remarked that he had seen and examined the patient and was struck with her emaciation, inquired of her sister if she had not lost a great deal of flesh since her marriage. This brought out three photographs, all of which represented a short woman of full habit, one of them having been taken two months before her marriage. The sister stated that the patient had no control over her evacuations from the rectum, and that she was being constantly soiled by their escape. But for the fact that the husband had been deprived of his prepuce in infancy, thereby rendering the penis callous, by the exposure of the glans to the air, it is hardly possible that he could have forced the organ through the flesh as he did, without so much personal suffering as to compel him to desist. Possibly also the tissues penetrated may have been less resist-

ing than normal. As the arm of a fœtus has been known to perforate the rectum and protrude at the anus during labor, without laceration of the perineum, there must be in some women a much less than usual strength in the rectal wall. In considering the emaciation of this woman during the eighteen months of her married life, the question naturally arises, was this condition due to the want of rectal alimentation, to the constant loss of fæcal matter, or to the depressing effects of her condition, weakening her appetite and rendering her life miserable? The opening through the fossa navicularis into the rectum, corresponded exactly with some of the cases of congenital malformation which Dr. Harris had met with, and particularly with one in a large stout primipara. In her, however, there was a slight anal sphincter, and except when affected with diarrhœa, she had control over her evacuations. The only case upon record which corresponded to this was operated upon by Sir Spencer Wells, in December, 1859, at the Samaritan Hospital.

Dr. Price remarked that eighteen gut sutures were introduced in closing the wound.

Dr. Chas. Meigs Wilson exhibited a

Fibroid Polypus of the Uterus.

This specimen was removed three weeks ago from the uterus of a patient with the following history: For the past three years she had been flooding almost constantly. Her flow had increased regularly at her catamenial periods, and at no time had it entirely ceased. She had suffered all that time agonizing pain, greatly increased during the menstrual period. The continued loss of blood had reduced her weight one-fourth, and the continued anæmia of her nerve-centres had produced characteristic effects. During all this time she had had given her all the agents of the pharmacopœia vaunted for their efficacy in controling uterine hemorrhage. But the cavity of the uterus had never been explored, save in a desultory way with a sound. When first seen she was extremely anæmic, emaciated, troubled with insomnia, and had a very irritable stomach. The uterus was dilated with the Elwood Wilson curved dilator. The growth, then readily seen, was grasped with a volsella, and dragged as far as possible from the uterus; a curved, crescentic-shaped, probe-pointed bistoury was then made to sweep over the surface of the growth until it came in contact with the sessile attachment of the tumor, which was severed with a sawing movement of the knife. Prior to the operation large doses of the fluid extract of ergot were given to the patient for forty-eight hours, in order to insure powerful contraction of the uterus after the tumor was removed. Immediately after the ablation of the growth, the cavity of the uterus was smeared with a solution of one part of Tait's iodine and two parts of pure carbolic acid. During the operation the patient lost half an ounce of blood. The removal of the tumor would undoubtedly have been accompanied by excessive hemorrhage had not the precaution been taken to secure prompt uterine contraction by the previous administration of ergot. The patient made a happy recovery, has lost no blood at all since the operation, has gained in weight, and improved in appetite. The case carries with it its own lessons. All the fruitless medication and the long period of suffering and distress might have been avoided had her medical attendants at the beginning dilated and explored the uterine cavity, removing the cause of the hemorrhage, instead of temporizing and making use of methods which at best, in cases of continued hemorrhage from the cavity of the uterus, are of a prophylactic nature. The polypus when fresh was four inches in length, two and a quarter in breadth, and one and three-quarters in thickness.

Dr. Goodell thought it was an error to expect hemorrhage after the removal of uterine fibroids. Velpeau had removed a very large number of these tumors, and his method had been to cut them away by means of a knife, and yet he had hemorrhage in two cases only. Dr. Goodell has removed very many of these tumors, and has employed every method; he has never had any trouble from hemorrhage. In Constantinople, while young in experience, and in consultation with another very young man, he saw a case in which auto-enucleation had commenced. The tumor was too large for removal by means of the ecraseur, as the vagina was so filled up that the wire could not be got up to the base of the tumor. They concluded to cut off all they could get at, and then gave ergot. The next day another large slice was removed, and at the end of a week they succeeded in dividing the false pedicle, and all was safely removed without any hemorrhage whatever. Since then he has ceased to fear hemorrhage, and thinks a danger is incurred by the use of ergot in causing contraction of the cervix uteri and incarcerating the tumor. He removes many submucous tumors by dilating the cervix with his dilator, passing in the polypus forceps, and accomplishing the diagnosis and removal at the same time, the

latter being effected by twisting. When he has recourse to the ecraseur, he now uses the finest piano-wire, which is more efficient than the heavier, and less likely to break. He first pushes the ecraseur up to the fundus uteri with the wire bent over, and then coaxes the wire up, and in this way has little trouble in getting it around the base of the tumor. Before tightening the wire he removes traction from the tumor, and pushes up with the ecraseur, so as to correct any inversion of the uterus that may have been caused in pulling the tumor down. Now when the wire is tightened the tumor will be divided witnout fear of injuring the uterine tissue.

Dr. Howard H. Kelly said the choice of method in these cases should depend largely upon the individual peculiarity. Chassaignac's ecraseur has rendered him good service in these polypi having broader bases of attachment, but when this is at the fundus and a large tumor chokes the vagina or cervix uteri, the difficulty of satisfactorily fixing the loop is very great. The chain added to the ecraseur by Marion Sims is serviceable, but nothing will compare with the flexible, easily-adjusted wire of a Braxton-Hicks ecraseur. Where the pedicle was neither large nor dense, he has had great satisfaction in the use of phosphor-bronze wire, which is so much more easily manipulated than piano wire. Scanzoni's plan of cutting the tumor off when the pedicle is long is excellent and safe. It goes without saying now, that rigid antiseptic precautions should accompany any such operation.

Dr. Parish did not think there was much difference in the methods of different operators. He never gives ergot before any intra-uterine operation in which he wishes relaxation of the cervix. With the ecraseur he uses wire, and introduces it in the manner described by Dr. Goodell, and uses jeweler's pliers to manipulate the wire, pushing it up and around the tumor. He has no fears of sepsis if all the tumor be removed, but he takes the precaution of injecting a very hot solution of mercuric chloride after operating.

Dr. Montgomery has had free hemorrhage after removing uterine fibroids by means of the ecraseur. This hemorrhage was so free in one case that hot water injections would not control it, and Monsel's solution was applied with success. He, however, would not give ergot beforehand, for fear of causing rigidity of the cervical tissues. In one instance a large piano wire snapped several times on account of the firm, dense character of the pedicle, and he had recourse to cutting away portions of the tumor, the remainder being thrown off by natural action. The tumor had been adherent to the posterior wall of the uterus, and had been partially enucleated before operation. The patient was very weak, and septicæmia and death resulted. In a case in which he used the wire ecraseur a portion of the tumor was left; it was thrown off by auto-enucleation, and was very offensive. The patient did not suffer from sepsis, but having wounded his own finger with a tenaculum in its removal, he was very sick in consequence. He thinks the spoon curette, or saw, would be the best instrument in the enucleation of large fibroids.

Dr. Goodell carefully cleanses out the vagina before and after operation. He formerly used carbolic acid, but now prefers the mercuric chloride. He prefers the high-note piano wire, which has never broken in his hands, as it cuts as well as crushes.

Dr. W. S. Stewart is glad to hear about the greater strength of the small piano wire, as he has been using triple-twisted wire, and has been much troubled by its breaking, so that he has given it up for the chain. He had mentioned his trouble to Gemrig, who recommended iron wire, which has been answering a very good purpose. He much prefers Labarraque's solution of chlorinated soda as an antiseptic and disinfectant.

Dr. Goodell remarked that the finer piano wire was not stronger, but was more efficient, as it cuts more easily through the tissues. Twisted wire will break more easily than single, because the strain on the different strands is unequal.

Dr. Baer agrees with Drs. Goodell and Parish as to the unadvisability of using ergot before operating. He has given up the ecraseur, on account of the difficulty attending the breaking of the wire. He is now in the habit of pulling down the tumor and removing it piece-meal. He uses vinegar, if a styptic is needed.

Dr. Wilson has seen one death follow the use of the ecraseur, and has had trouble in adjusting the wire; the liability of removing uterine tissue by the wire is a great danger. He thinks it better to drag the tumor down and cut it off in pieces. He feared hemorrhage in this patient, on account of the fearful loss of blood which she had already sustained. He considered prophylaxis the safer course.

Vaginal Hysterectomy.

Dr. Wm. Goodell exhibited a womb which he had removed per vaginam. The woman had been brought to him by Dr. F. R. Ger-

hard, of Douglassville, Pa. She was sixty-five years old and had given birth to twelve children. She had a hypertrophied elongation of the womb, the sound giving a measurement of minus five inches; her cervix was outside of her body, and it was very greatly enlarged in every direction by a carcinoma. On March 10, before the students of the University of Pennsylvania, he amputated the cervix after applying an elastic ligature; but finding that Douglass's pouch had been opened, he concluded to perform the radical operation. The womb was accordingly retroverted, its attachments to the bladder severed, the broad ligaments tied *en masse*, each with two strong ligatures, and the womb removed. The large gaping wound was closed by seven wire sutures, leaving only a small opening through which the ligatures passed, and acted as drainage tubes. Sublimated cotton was lightly packed into the vagina. This was removed twice a day and the wound syringed out with a one-to-two-thousand solution of mercuric chloride. On the next day, the temperature rose to 100.2°, but it never after that day reached 100°. The sutures were removed on the fourteenth day, and with some difficulty, as they were now high up in the apex of a cone-shaped vagina. She was able to go home on the twenty-third day after the operation.

Dr. H. A. Kelly remarked that he wished in this connection to emphasize a point of vital importance in every operation where there is either artificial or pathological descent of the cervix proper. The slightest traction, elongating the cervix, draws the vaginal vault down over the displaced supravaginal portion, like the finger of a glove, and unless especial care is directed to this point, there is imminent danger of scalping the vagina in any operation then performed on the cervix. In lacerated cervix, particularly where Dawson's scissors are used (and great downward traction is fashionable), and the bases of the broad ligaments are opened in this way, and in amputation intended to be limited to the infra-vaginal cervix, as in this case of Dr. Goodell's, either the scalping process lays bare a broad tract of areolar tissue in the vault around the cervix, or, worst of all, Douglass's pouch is laid open. It is unnecessary to enlarge upon the greatly-increased dangers of septic infection. He would ask Dr. Goodell in regard to the after-treatment of this case. In the latest contribution to this subject by Dr. Brennecke, of Magdeburg, in the *Zeitschrift für Geburtshulfe und Gynecologie*, he clearly shows that those cases ran a most favorable course in which the iodoform tampon was not removed for six or seven days, and that syringing after operation with a view of carrying off foul discharge is a pernicious practice, as it separates the peritoneal surfaces which have just formed delicate adhesions, and breaks up the early steps of repair, without the possibility of accomplishing its purpose. A point well worth attention is Brennecke's method of dealing with the upper part of the stump of the broad ligaments which are caught in stout ligatures. Experience has shown that the distal end is very apt to slough, and to secure an immunity from dangers of sloughing, Brennecke ties the ligatures of opposite sides across, and everts the two stumps, thus fastened together, into the vagina where they cannot do harm, and help form a plug for the wound.

Dr. Montgomery questions the propriety of total extirpation of the uterus. How long is the patient likely to live after this operation? If partial removal gives equal relief from the disease for which the operation is performed, and an equal or greater chance for a prolongation of life, it is to be preferred as the least dangerous. Hoffmeier, in a summary of German gynecological work, opposes total extirpation if it can be avoided. He reports 145 cases of partial, and 39 of total removal of the uterus. Ten of each series were fatal. In six of the partial cures the result was unknown. Of the total removals six only were living at the end of two years, and none at the end of three years; while of the partial, six still lived at the end of the fifth year. Following the plan suggested by Sims and Van de Warker, in cases of malignant disease of the cervix, Dr. Montgomery makes an incision into the uterus at the vaginal junction and dissects upward as closely as possible to the peritoneal surface, while making traction on the cervix; thus, as it were, enucleates the uterus, leaving a very thin wall; he then stuffs this cavity with a mixture of equal quantities of zinc chloride and water on cotton tampons, to cause a slough of any diseased tissue that may have been left behind. If by chance the sloughing should perforate the peritoneum, the previous inflammatory exudation would save the peritoneal cavity from invasion.

Dr. H. A. Kelly does not wish the claim of an eminent American surgeon to priority in this matter to be forgotten. The credit of originating the highest practicable cone-shaped amputation of the uterus, and establishing its great utility, its safety and rela-

tively greater success, is due to Dr. Baker, of Boston. He uses no cautery, and controls hemorrhage perfectly by the effect of the strong downward traction upon the vessels.

Dr. Parish mentioned an earlier operation by Hirth, of San Antonio, Texas, who practiced the method, described by Dr. Montgomery, of enucleating the uterus from its peritoneal covering. He divided the vaginal mucous membrane, and gradually shelled or scooped out the uterine tissue. The operation was accompanied by great hemorrhage.

Dr. C. M. Wilson thought such an operation very dangerous, and liable to be followed by secondary hemorrhage. He has in two cases after Dr. Baker's method used a hot tamponade of the uterus and vagina after the operation. Dr. McCormick, of London, packed the stump with bandage or gauze filled with iodoform, and allowed it to remain undisturbed for nine days. This was perfectly sweet when removed, and is a good and safe plan of after-treatment.

Dr. Goodell said the method of Brennecke's of not washing seemed to him to be undoubtedly a good one, and he would in future adopt it. He once had an alarming hemorrhage from the division of a large vessel after a hole had been accidentally made in Douglass's cul-de-sac in the high amputation. Consequently, he could not pack the vagina for fear of forcing blood, etc., into the peritoneal cavity, and he had to control the bleeding by twisting a wire around it. He generally uses Paquelin to control hemorrhage in these cases, and has operated upon at least 200 with only four deaths. Neither of the fatal cases were high operations. One death was from secondary hemorrhage, one from tetanus, one from a frank peritonitis, and one from septicæmia. He thinks the high operation the most feasible one in the majority of cases in which the womb is movable, and he has extirpated the womb but twice for carcinoma.

Dr. H. A. Kelly exhibited the sac of an

Ovarian Tumor that Weighed, at Removal, 100 Pounds.

Dr. Goodell congratulated Dr. Kelly upon his success in removing such a large tumor. He, Dr. Goodell, had on one occasion removed a tumor weighing 112 pounds from a woman who, after the operation, weighed only 74 pounds. As in Dr. Kelly's patient, the tumor reached the patient's knees and she could not lie down. After the operation, the large folds of the stretched skin were a great annoyance, but after some months it had entirely contracted. The patient made a complete recovery.

Dr. M. Price had been present at Dr. Kelly's operation. A large vein was torn and a stream of blood as large as his finger poured out. The patient collapsed instantly and Dr. Price thought her dead, but he was surprised and pleased at the effects of a hypodermatic injection of f.ʒj. of sulphuric ether, which restored the pulsation quickly.

(*To be continued*).

CHICAGO MEDICAL SOCIETY.

(*Concluded from page* 750.)

Dr. R. Tilley said he did not consider electrolysis to be the proper term to be used in connection with the use of electricity in the manner suggested. Electrolysis, in the ordinary acceptation of the term, means the decomposition by electricity of water, or tissues, being in the nature of a chemical decomposition. He would like to know how far apart the electrodes were placed. (Dr. Belfield replied that the negative electrode was placed in the urethra, and the positive pole in any position on or near the penis, according to the effect intended.) He could not see how electrolysis could be produced with the electrodes so far apart, and a weak fluid, without a cauterizing effect. From his extensive experience of cocaine in producing contraction of the tissues in the nose, he would expect to secure as good, if not better results, reasoning by analogy, in its use in strictures of the urethra as in the use of electricity. He would think its internal application would be followed by wonderful results.

Dr. W. T. Belfield closed the discussion by saying that in reply to Dr. Fenger's criticism that these strictures were not impermeable, he would remind him that he called six of them "theoretically permeable, practically impermeable;" that is, a feeble stream was forced through, but no instrument could be introduced. The remaining three were absolutely impermeable to urine as well as instruments. They were water-tight, the bladder in each case being immensely distended. Dr. Fenger, in the cases where he attempted electrolysis, evidently made the usual mistake: he employed a strong current and *cauterized*, but did not electrolyze, the stricture. With a proper current he would probably have a better result. Sir Henry Thompson and Prof. Dittel do not, it is true, endorse electrolysis; but he knows that neither of them has ever fairly tried it; they have contented themselves with the vague, unfavorable verdict of those who,

having once or twice misused the current, attribute to the battery the faults which belong to themselves. Thompson's conservatism and intolerance are notorious; he bitterly opposed Bigelow's litholapaxy (without trying it) until it was adopted by everybody else. Possibly, as Dr. Fenger says, there is no "urgent necessity" for any other method than urethrotomy and dilatation; but surgeons who have to treat many such strictures as those described in the paper under discussion, think otherwise. These methods certainly possess one point of national economic value which electrolysis lacks, namely: they assist in repressing the excess of population by quietly removing many patients.

Electrolysis "bobs up" and down only when ignorantly used; when properly employed it comes to stay.

To Dr. Tilley he would say that the action is properly termed "electrolysis;" it is the same effect as is seen in the decomposition of water, and is produced by the same current. During the action of the current a white foam and bubbles come up alongside the instrument. Cocaine causes contraction of blood-vessels in the urethra as well as in the nose; but it cannot, so far as he is aware, remove cicatricial tissue in either locality.

In conclusion, he would repeat that the secret of success lies in securing chemical force and avoiding heat; the former removes the stricture easily and painlessly, the latter causes violent inflammation and sloughing.

Osteo-plastic Resection.

Dr. C. Fenger then presented a patient before the Society with the following words: I wish to bring this patient before the Society to illustrate the results of an operation called "osteo-plastic resection of the foot," and devised by Wladimnoff and Mikulicz. The operation consists in removal of the heel, soft parts and bones, and then uniting the remainder of the foot to the tibia in the position of an artificial pès èquinis. As you will see, the patient has on a plaster cast from the toe to below the knee, and is able to walk in this cast without crutch or cane. He limps because the leg operated upon is two inches longer than the other one, and not because of inability to step on the leg. He will have in future to wear a high sole or heel under the well foot. While this plaster cast is being taken off, I shall pass round the specimen of the removed heel and say a few words about the operation.

The patient had suffered for one year from a chronic traumatic osteomyelitis of the tarsus, resulting in anchylosis of the joints, fistulæ on dorsal side of tarsus, and a loss of substance of the skin of the heel. Piragoff's or Syme's operation being out of the question, the choice was only between a supramalleolar amputation and the osteo-plastic resection. This operation was performed fourteen months ago. Union of the bones took place in four to six months, and it is only the subsequent small operations for bringing the toes in dorsal flexion that have required so long a time before the patient has been able to commence to walk.

The plaster cast being now removed, you will find the foot in the axis of the leg in equinus position, the toes dorsally flexed to a right angle with the foot. There is active flexibility of the toes and some active mobility of the foot. This mobility, however, does not take place between the united surfaces of the tibia and fibula on the one side, and the scaphoid and cuboid bones on the other, as can be seen by examining the prominences representing the rudimentary newly-formed malleoli—but the mobility takes place in the joints of the metatarsus. As to the question whether these joints will be able to bear the strain of the weight of the body during walking with the foot in this abnormal position, this patient of course proves nothing as yet. But from the other cases operated upon, in all nineteen, we can conclude that we have the right to expect a useful foot for walking. A patient operated upon by Socin, in Basle, is able without boot—the boot devised by Mikulicz, which I now pass round for inspection—or cane to walk, but can walk all day long and perform a farmer's work in the field. You will further notice that the walking surface of the foot, being the plantar surface of the heads of the metatarsal bones and the toes, is considerably larger than the surface which either a Syme's or a Piragoff's operation would leave the patient to walk on. This, together with the active mobility of the toes, is regarded as an advantage that functionally places the osteo-plastic resection superior to the two other operations mentioned.

We find by examining the foot everywhere painless on pressure, and consequently there is nowhere any recurrence of the disease.

Mikulicz feared that the anterior tibial artery might not be sufficient for the blood-supply of the foot, his method of operating dividing all the branches of the posterior tibial artery. I had the same apprehension, and changed the incision so as to save one of the terminal branches of the last-named vessel, namely, the internal plantar artery.

This fear is not unfounded, as in one of Sordina's cases operated upon according to Mikulicz's description, gangrene of the foot necessitated supramalleolar amputation on the fourth day. The mortality of the operation is as yet none, but as all the nineteen cases have fallen within the last few years except Wladimnoff's, and consequently have been treated antiseptically, it cannot be said that the danger is less than either in Syme's or Piragoff's operation. There is no doubt that the functional results are far superior to that of a supramalleolar amputation, even if the patient will always have to wear the Mikulicz boot. Consequently it may be safe to say that osteo-plastic resection has already a legitimate place, although perhaps as yet not strictly enough defined, in the surgery of the tarsus.

The Society adjourned.

Periscope.

Hair-pin in the Sigmoid Flexure.

In the *Rev. Med. de l' Est*, Dr. Th. Weiss reports an obscure illness in a boy æt. twelve. The child when first seen was lying with the left thigh flexed, adducted, and slightly rotated inwards; his face was pale and anxious, diarrhœa was frequent, and there was some fever towards evening. Hip disease was diagnosed, and under chloroform the limb was put up in silicate, its position being previously corrected. Some days afterwards, a collection of pus formed in the lumbar region behind the iliac crest; on being opened much pus escaped, and it was found that the finger could be swept over the iliac fossa, but no foreign body was felt. It was now thought that the abscess was caused by inflammation extending into the cellular tissue around the sigmoid flexure, and that it had probably started in the gut. Another abscess formed and was opened by the great trochanter; about a month afterwards, December, 1883, the discharge from the lumbar wound became fæcal, and soon all the fæces were passed through this opening. Matters continued thus till the child was attacked with erysipelas, after which the sinuses almost closed. In January, 1884, the boy was up and continued well till May, when both fistulæ broke out again, giving exit to pus and fæces. In a short time the symptoms subsided, but in July a third and similar attack nearly terminated fatally, owing to the profuseness of the suppuration. In August a fresh abscess was discovered in Scarpa's triangle; this was opened, and while trying to pass a drainage tube through to the lumbar incision a hard body was found, which on removal was found to be a very distorted and roughened large hair-pin. The boy, on being questioned, remembered that three years previously he had endeavored to relieve some anal itching by scratching himself with a hair-pin; this suddenly disappeared and he thought it had fallen on the ground, and as he experienced no trouble, the fact escaped his memory till he again saw the pin. Eventually the boy made a good recovery and could walk fairly well, the thigh being still a little flexed on the abdomen, though this is improving under extension by night. In commenting on the case, Dr. Weiss states that at one time he suspected that a foreign body taken through the mouth might be the cause of the mischief, but he gave up this view owing to the body usually being arrested near the cæcum and setting up perityphlitis. It is curious that one year elapsed before any trouble ensued, and two before the abscess formed. Poulet affirms that this tolerance by the rectum of foreign bodies is exceptional, as surgical interference is usually necessary, owing either to intestinal obstruction or spasmodic pains. Gérard has collected thirty-four cases of the introduction of foreign bodies into the rectum; in seventeen cases they remained *in situ*, the remainder traveled to some part of the large intestine. Those which entered with the pointed end first, and whose circumference was more than eighteen centimetres, seldom reached the sigmoid flexure, because they were stopped by the point catching in the mucous membrane or by the rectal bend at the sacro-vertebral angle. The hair-pin entered by its rounded end, and so would have a natural tendency to mount towards the sigmoid flexure, as the points catching in the mucous membrane would prevent its descent. The danger of peritonitis is great, and Weiss advises that if a foreign body is detected: (1) it should be removed per rectum; failing this (2) the surgeon, following the practice of Verneuil, should perform laparotomy and push the foreign body down to the rectum,

previously enlarged if necessary by linear rectotomy. If unsuccessful, (3) by enterotomy followed by suture of the intestine.

Meningitis after Ear Disease.

Before an English medical society Dr. Michie read notes of three cases of meningitis following disease of the middle ear. The first was that of a child 14 months old, who had occasionally suffered from purulent discharge from the right ear. After the discharge had lasted sixteen days, it suddenly stopped, and cerebral symptoms supervened. The child became careless of everything around, lay in bed with the head extended and the eyes staring, took nourishment only when pressed, and had disturbed nights. The breathing became cerebral, the temperature rose to 101° Fahr., and the pulse to 130. The abdomen became retracted, and tremors of the fingers and toes were noticed. Towards the end, retinal hemorrhages were seen with the ophthalmoscope, and convulsions occurred ten hours before death, which resulted in ten days after the occurrence of brain-symptoms. The treatment consisted in the administration of grey powder and bromide of potassium, and the application of iodoform ointment to the shaven scalp. The second case occurred in a lad, aged 13, who had suffered from purulent tympanitis of the right ear for six months. Severe pain suddenly set in in the right ear, and he became pale and unconscious for a few minutes; but, on recovering, he was able to walk home. During the next four days, the pain became intense, especially over the mastoid. The tonsils and pharynx were inflamed; the watch was heard only on contact, and the perforation in the membrane was covered with granulations. The pain diminished; the patient was well for two days, when, after injudicious exposure, the pain recurred with increased severity, with intermissions and violent exacerbations, rendering the patient delirious. During the intermissions, which gradually became shorter, he was calm and rational. A prolonged rigor, followed by deep coma, came on three hours before death, which took place three days after the second attack. The third patient was a woman, aged 20, who had suffered since childhood from purulent discharge from the left ear. In 1883, a polypus was removed from the left ear. In September, 1885, along with pharyngeal catarrh, severe pain set in in the left ear and mastoid region, accompanied by high fever, vomiting and rigors; it was only partially relieved by a discharge of fœtid pus. After a fortnight, there were marked prostration, and an œdematous condition of the eyelids of the affected side and lower half of the ocular conjunctiva, followed five days later by a herpetic eruption over the whole left side of the face. During the same time, the right side of the face became similarly affected. The herpes ran its usual course, disappearing in thirteen days. The tongue got dry and leathery, the intellect became confused, and there was marked hyperæsthesia and occasional delirium. In the fourth week the hyperæsthesia diminished, and the patient became comatose. The discs became hyperæmic, and retinal extravasations were noted. The coma gradually deepened, and death took place on the thirty-first day. Treatment consisted in frequent syringing with warm water, fomentations, and sedative applications externally, and bromide of potassium internally.

Purification of Water: its Biological and Chemical Basis.

The *Brit. Med. Jour.*, April 17, says:

In a paper thus entitled, which was read before the Institution of Civil Engineers on the 6th April, Dr. Percy F. Frankland describes his method for detecting the relative freedom from micro-organisms of different waters, or of the same water at different times, by Koch's process of cultivation upon films of nutritive gelatine. Perhaps the only weak point in Dr. Frankland's deductions, from the observed results obtained by his process, is that he asserts that the number of "colonies" of organisms produced upon the film are a direct indication of the actual number of organisms present in the original water, each "colony" being supposed by him to originate from a single organism. Now, it is clear that several organisms might be collected upon one spot of the film at the moment when the water was poured upon it; and from these, but one colony would result. However, there seems little doubt that the number of colonies must be an indication of the relative abundance of organisms in the water from which they are derived. Several very important practical results are arrived at, and emphasized in the paper. For instance, it has been found that even coarse-grained filtering materials, such as sand, are efficient in removing micro-organisms from water, although the channels which exist therein are too large to arrest mechanically the passage of these minute bodies. The same filtering agent, however, cannot be used for an in-

definite time, for the organisms diffuse out of it after awhile, and become once more distributed through the water. Dr. Frankland takes five of the London water-companies, and classifies them according to the excellence of their provision for water-purification in four particulars, namely:

1. Storage-capacity of unfiltered water.
2. Thickness of fine sand for filtration.
3. Rate of filtration; and,
4. Frequency of renewal of the filter-beds.

And he finds that the number of micro-organisms found in the water supplied by these companies is smaller in proportion to the perfection of their arrangements in these four points combined. It is to be hoped that the nature as well as the number of the organisms present in drinking-water may be studied more universally than hitherto, by the aid of Dr. Frankland's process, which seems to be simple and practicable.

Hysteria and its Relation to Diseases of the Uterine Appendages.

Dr. S. C. Gordon thus concluded a paper before the American Medical Association:

I. That these (so-called) hysterical symptoms occur almost exclusively in women. That whenever any of them do occur in men they are much less in degree, even if they do not differ in kind.

2. That it is fair to presume from the first propsition that it is due to disease of some organ or organs peculiar to women.

3. That they are not due to disease of the uterus alone, for when all apparent abnormalities of the uterus are corrected, the symptoms, very often, are not in the least relieved.

4. That all modes of treatment, other than operation, have failed to cure, and in most instances have not ameliorated, the symptoms, even where the disease was believed to exist in the uterine appendages.

5. That the large majority of all cases operated upon have been entirely cured of the symptoms for which the operation was made, and the remnant have been relieved and are continuing to improve.

6. That it is impossible, in a majority of cases, to determine by the touch, disease of these organs that will produce the symptoms alluded to.

7. That one can by these symptoms alone make a sufficiently satisfactory diagnosis to warrant the operation.

8. That if after correction of all well known and clearly diagnosticated uterine troubles, these symptoms are not relieved, we are justified and required, for the cure of our patient, to recommend this remedy.

9. That the operation does not in any case destroy the sexual desire, or in any way unsex the woman, except so far as it may prevent further child-bearing.

10. That in a majority of cases requiring the operation the woman is already sterile.

11. That in my own experience the specimens removed have been found so changed by inflammatory action as to be cirrhotic, or otherwise destroyed, either by softening or cystic degeneration of both ovaries and tubes, with very frequent stenosis of the latter.

12. That a fatal result from the operation is extremely rare, if it is carefully performed and closely and intelligently managed as to the after treatment. In the twenty-five cases operated upon there has been but one death.

Manicure.

The *New York Analyst* says: There are not nearly as many secrets in manicure as people imagine. A little ammonia or borax in the water you wash your hands with, and that water just lukewarm, will keep the skin clean and soft. A little oatmeal mixed with the water will whiten the hands. Many people use glycerine on their hands when they go to bed, wearing gloves to keep the bedding clean; but glycerine don't agree with every one. It makes some skins harsh and red. These people should rub their hands with dry oatmeal, and wear gloves in bed. The best preparation for the hands at night is white of egg, with a grain of alum dissolved in it. Manicures have a fancy name for it; but all can make it and spread it over their hands, and the job is done. They also make the Roman toilet paste. It is merely white of egg, barley flour, and honey. They say it was used by the Romans in olden time. Anyway, it is a first-rate thing; but it is a mean, sticky sort of stuff to use, and don't do the work any better than oatmeal. The roughest and hardest hands can be made soft and white in a month's time by doctoring them a little at bed-time, and all the tools you need are a nail-brush, a bottle of ammonia, a box of powdered borax, and a little fine, white sand to rub the stains off, or a cut of lemon, which will do even better, for the acid of the lemon will clean anything. Manicures use acids in the shop, but the lemon is quite as good, and isn't poisonous, while the acids are.

Shoulder-joint Friction and Incipient Phthisis.

Dr. Angel Money thus writes in the *Brit. Med. Jour.:*

My object in this brief communication is to draw attention to a certain physical sign that not unfrequently leads to error. As the first physical sign of incipient phthisis is frequently a mere adventitious sound heard over some part of the apex of the lung, and as the friction produced in the shoulder-joint by breathing often imitates very closely these pulmonary adventitious sounds, it is not difficult to understand how mistakes in diagnosis should occur.

I think that there are good grounds for believing that lives are sometimes rejected at insurance offices from want of knowledge on this point.
